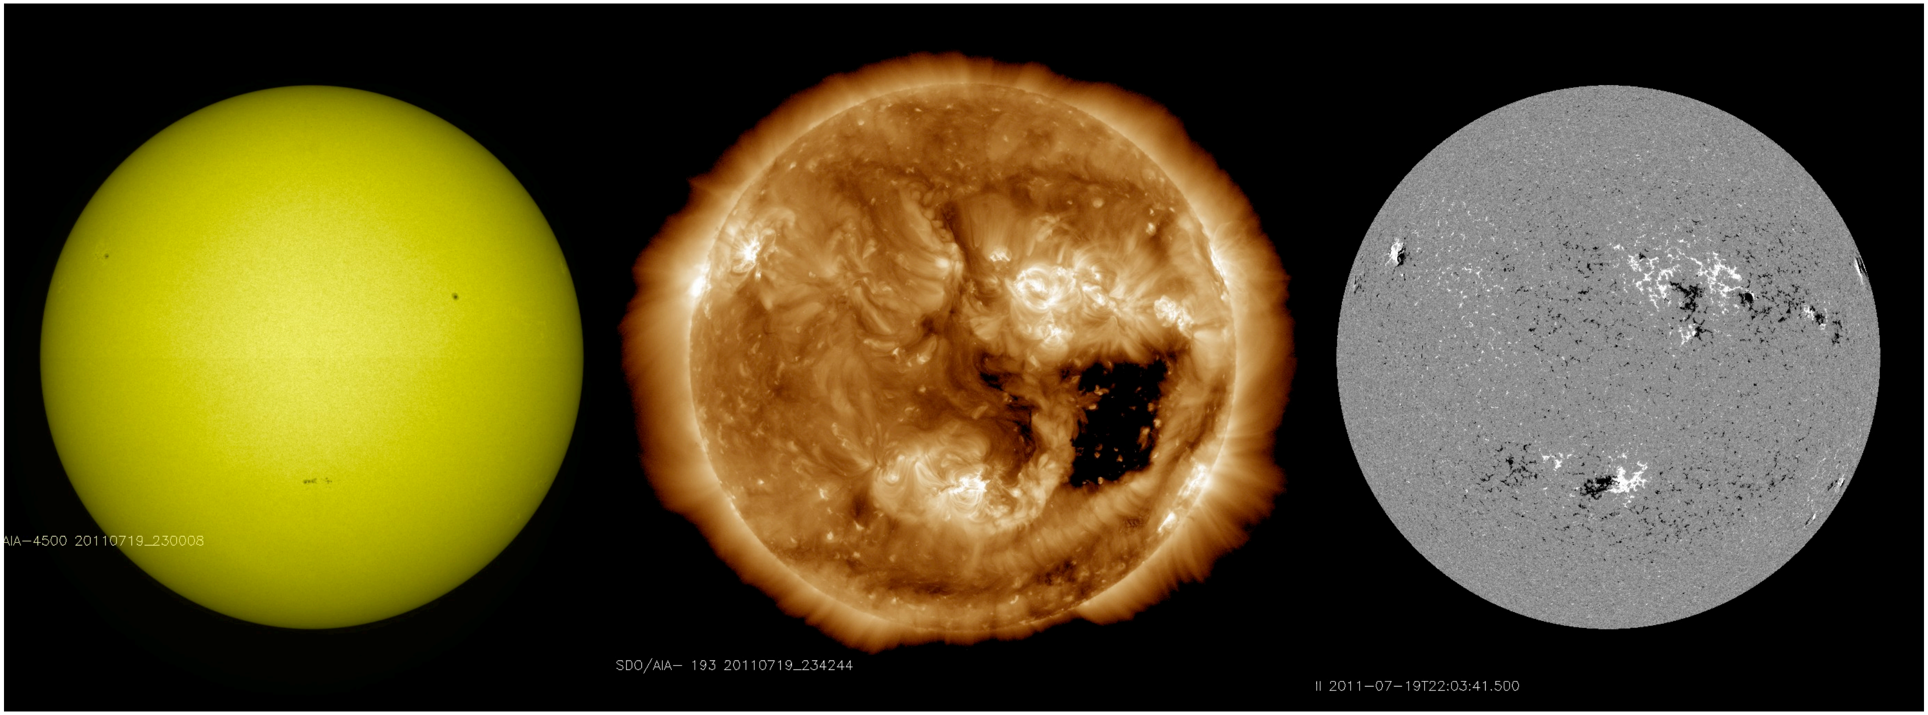
# Q: Why does the Sun have a Corona? A Wind?

Dana Longcope

Montana State University

With liberal “borrowing” from Hansteen, Schrijver, Gosling, Jokipii, Giacalone, Lean, …

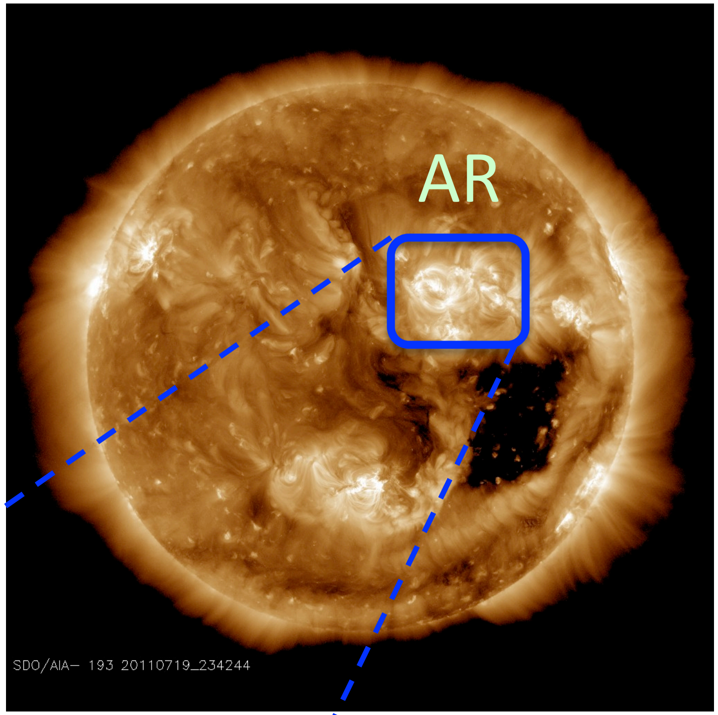


**Coronal (EUV) imaging – the basics:**

- what you see is all the same T (1.5 x $10^6$ K)
- bright = dense plasma – $n_e^2$
- heating **can*** make plasma dense & thus bright
- heating is evidently magnetic

* if magnetic field lines are closed – magnetic bottle

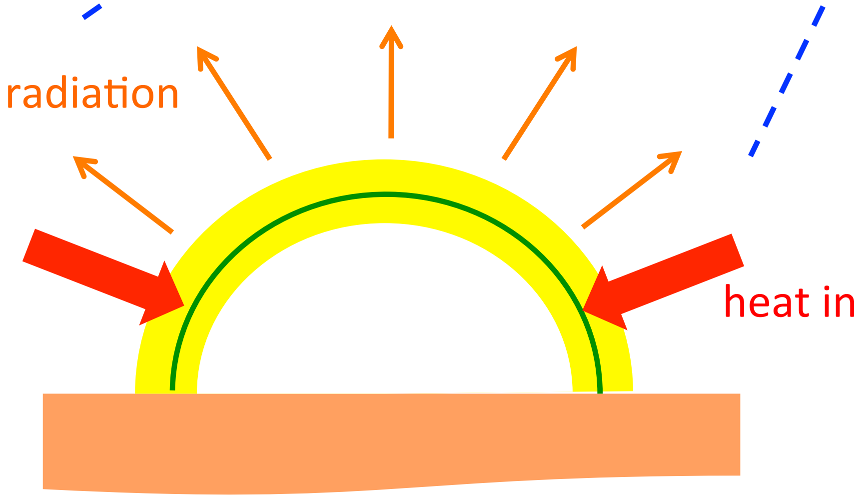
**B** large enough to restrict plasma motion: only along field lines

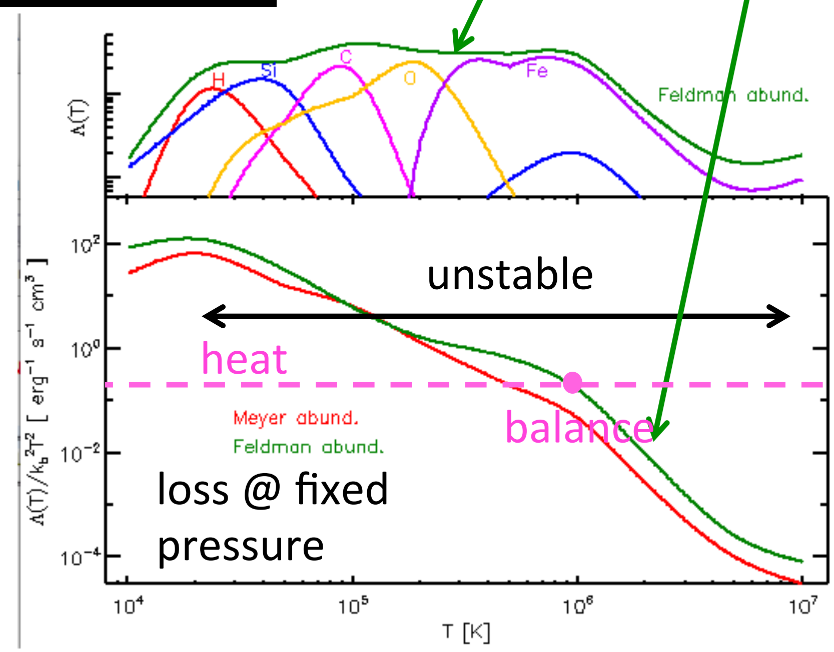


0d picture:
balance between
heat & radiation
@ fixed pressure

Radiative losses per volume:
Eq. (8.6)

$$n_e n_H \Lambda(T) = p^2 \frac{\Lambda(T)}{k_b^2 T^2}$$



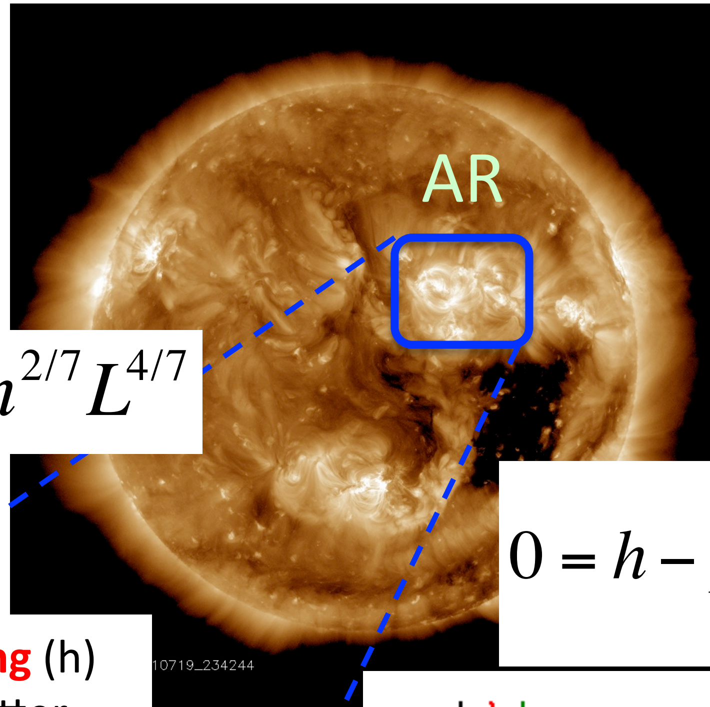


balance:
(RTV)

$$p \sim h^{6/7} L^{5/7}$$

$$T_{\max} \sim (pL)^{1/3} \sim h^{2/7} L^{4/7}$$

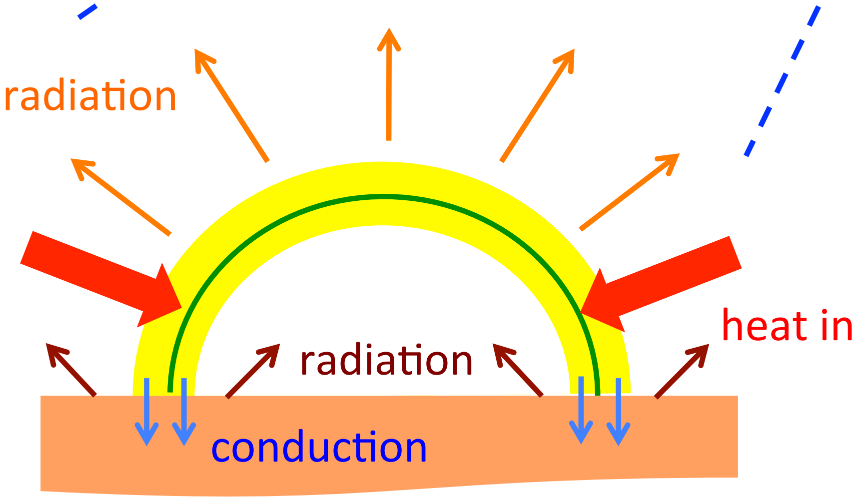
$$I \sim n_e^2 \sim h^{8/7} L^{2/7}$$

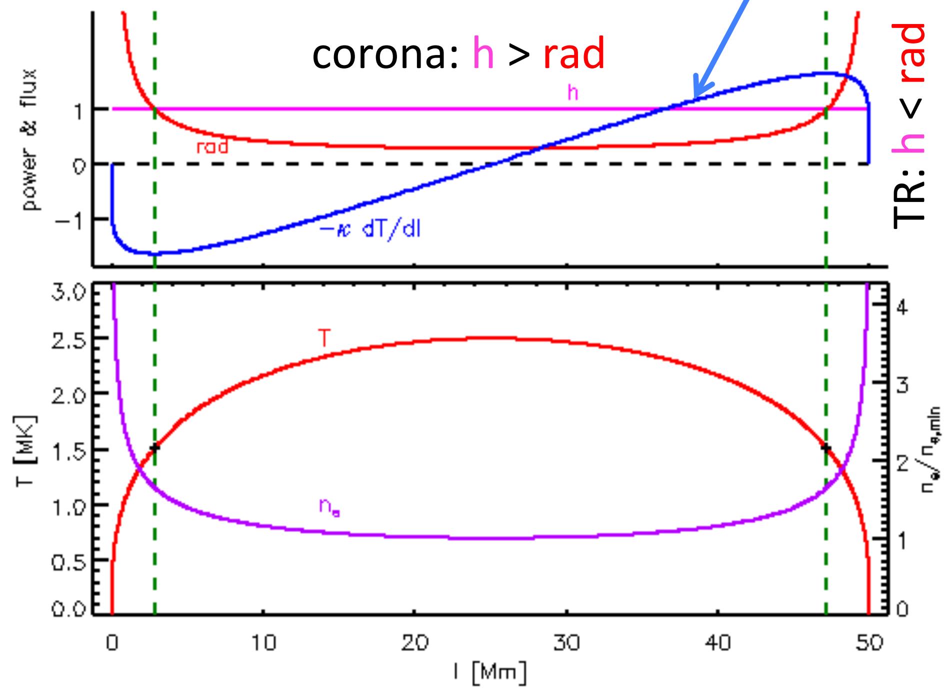


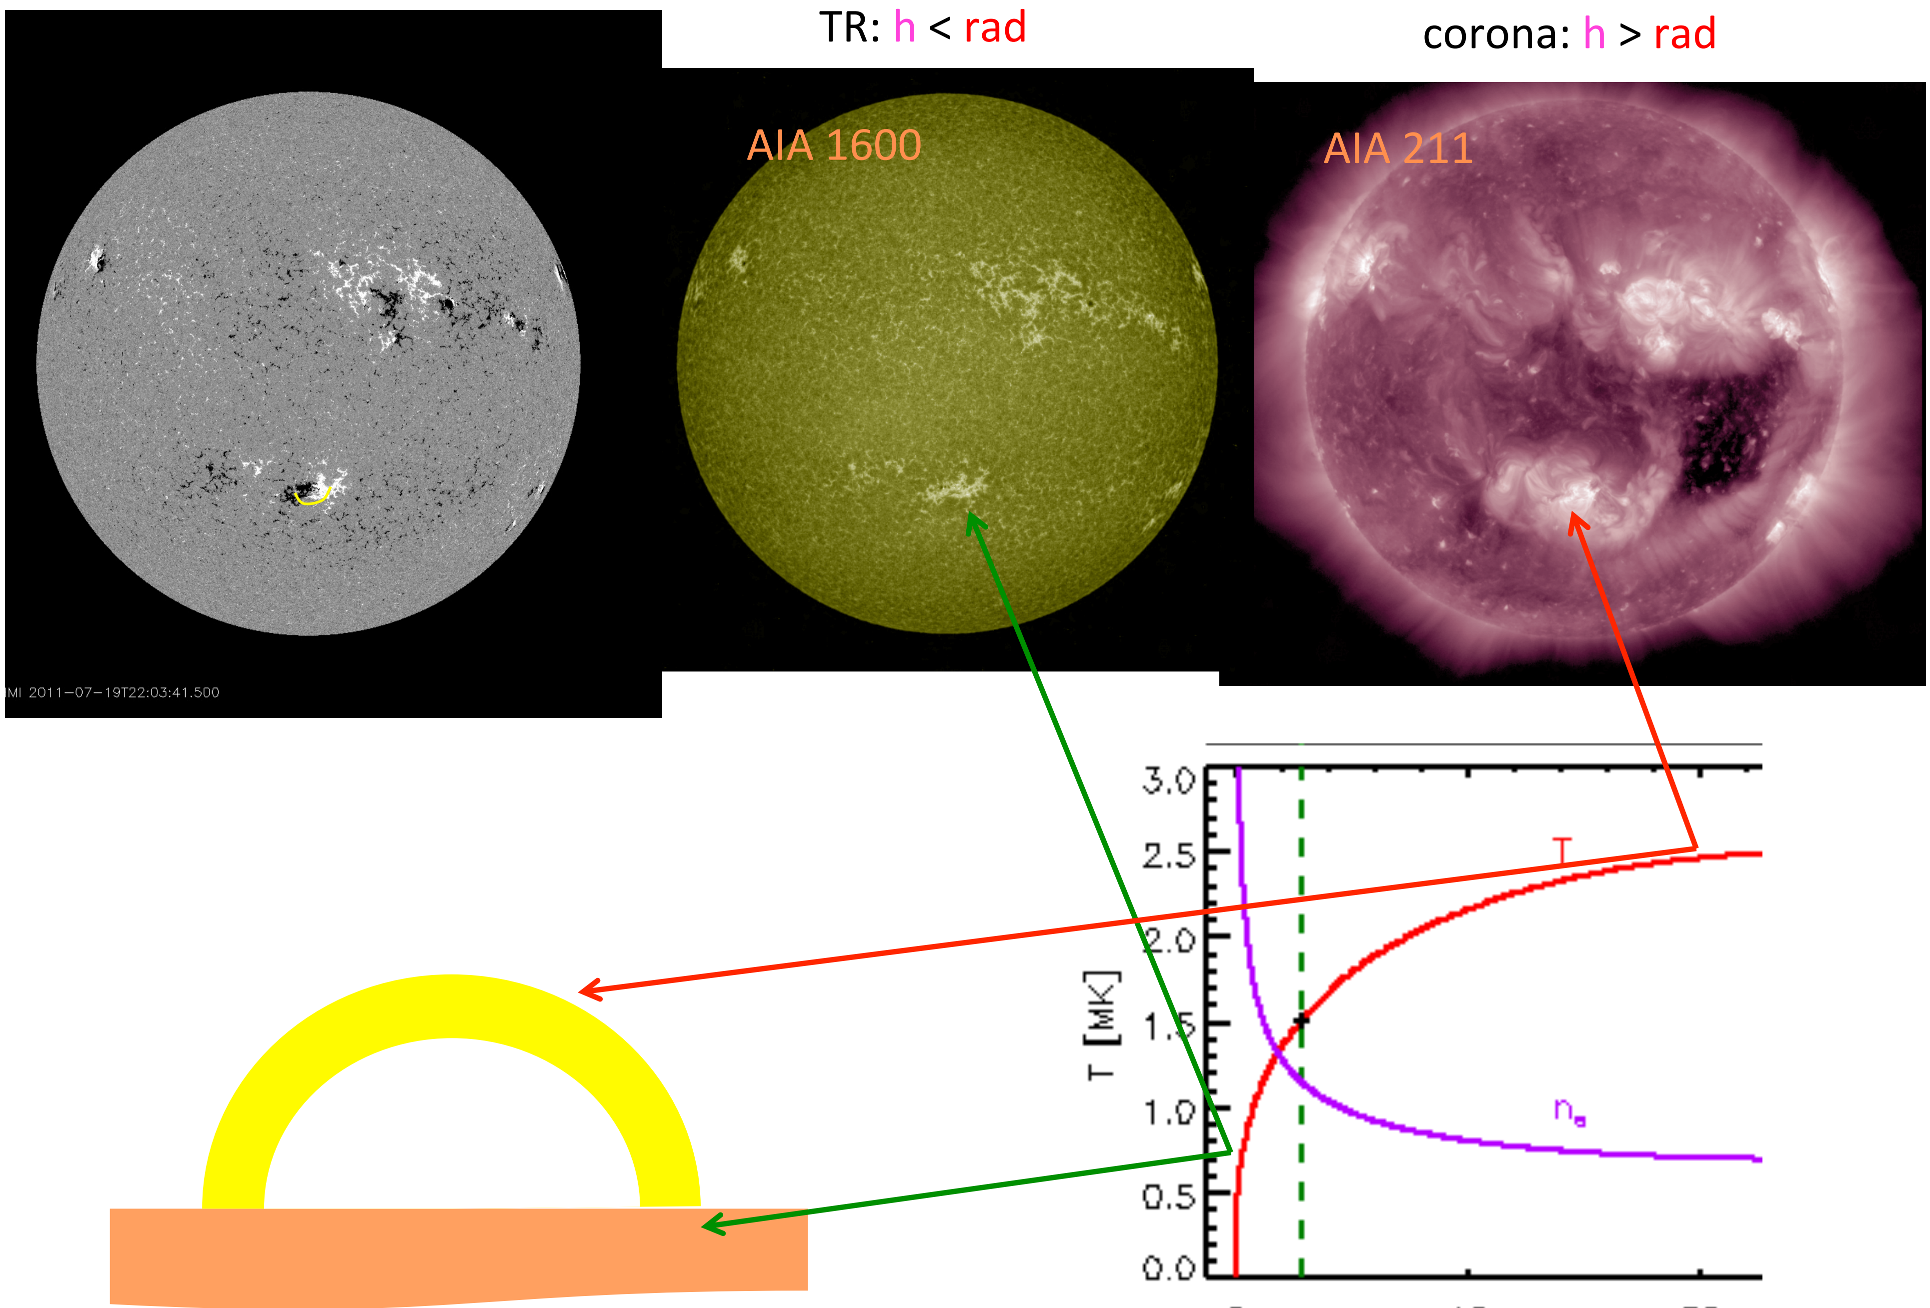
Need 1d:
include thermal
conduction to
move heat to
chromosphere

$$0 = h - p^2 \frac{\Lambda(T)}{k_B^2 T^2} + \frac{\partial}{\partial \ell}\left( \kappa \frac{\partial T}{\partial \ell} \right)$$

**more heating** (h)
➔ little hotter
much brighter







TR: h < rad
corona: h > rad

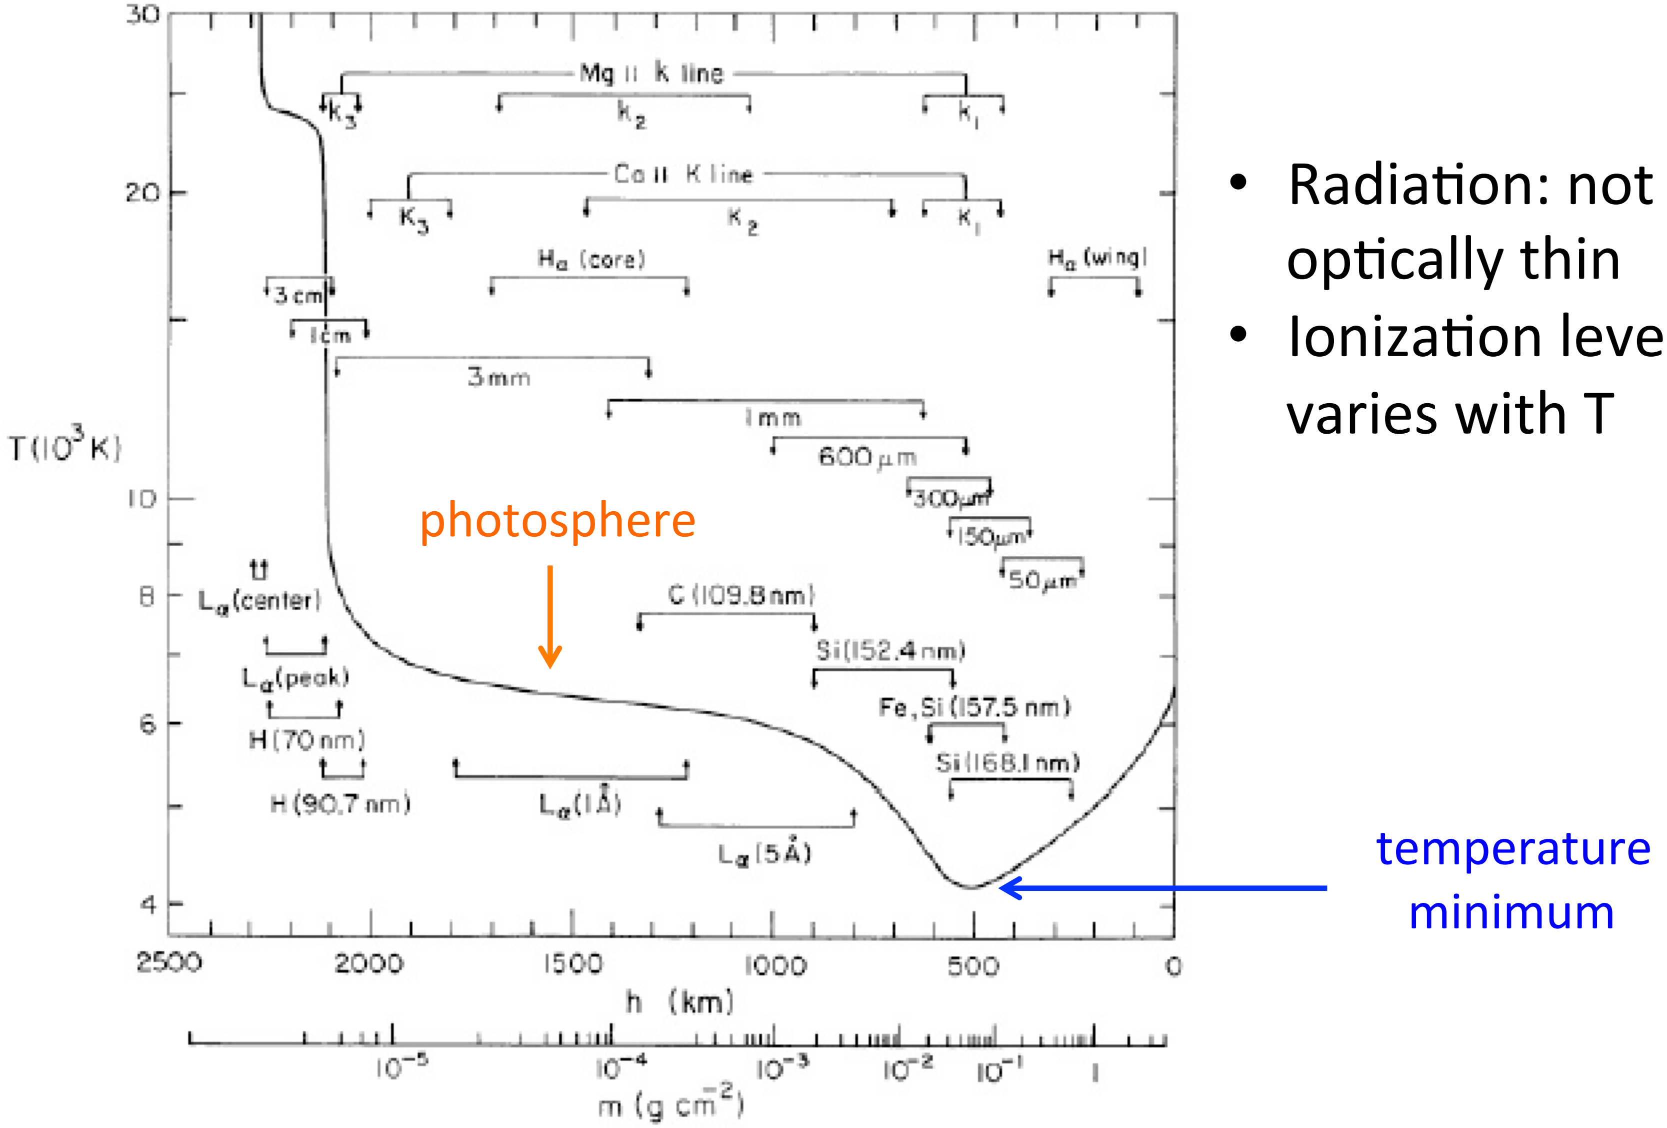
T
$n_e$

# Below the TR – hairy details

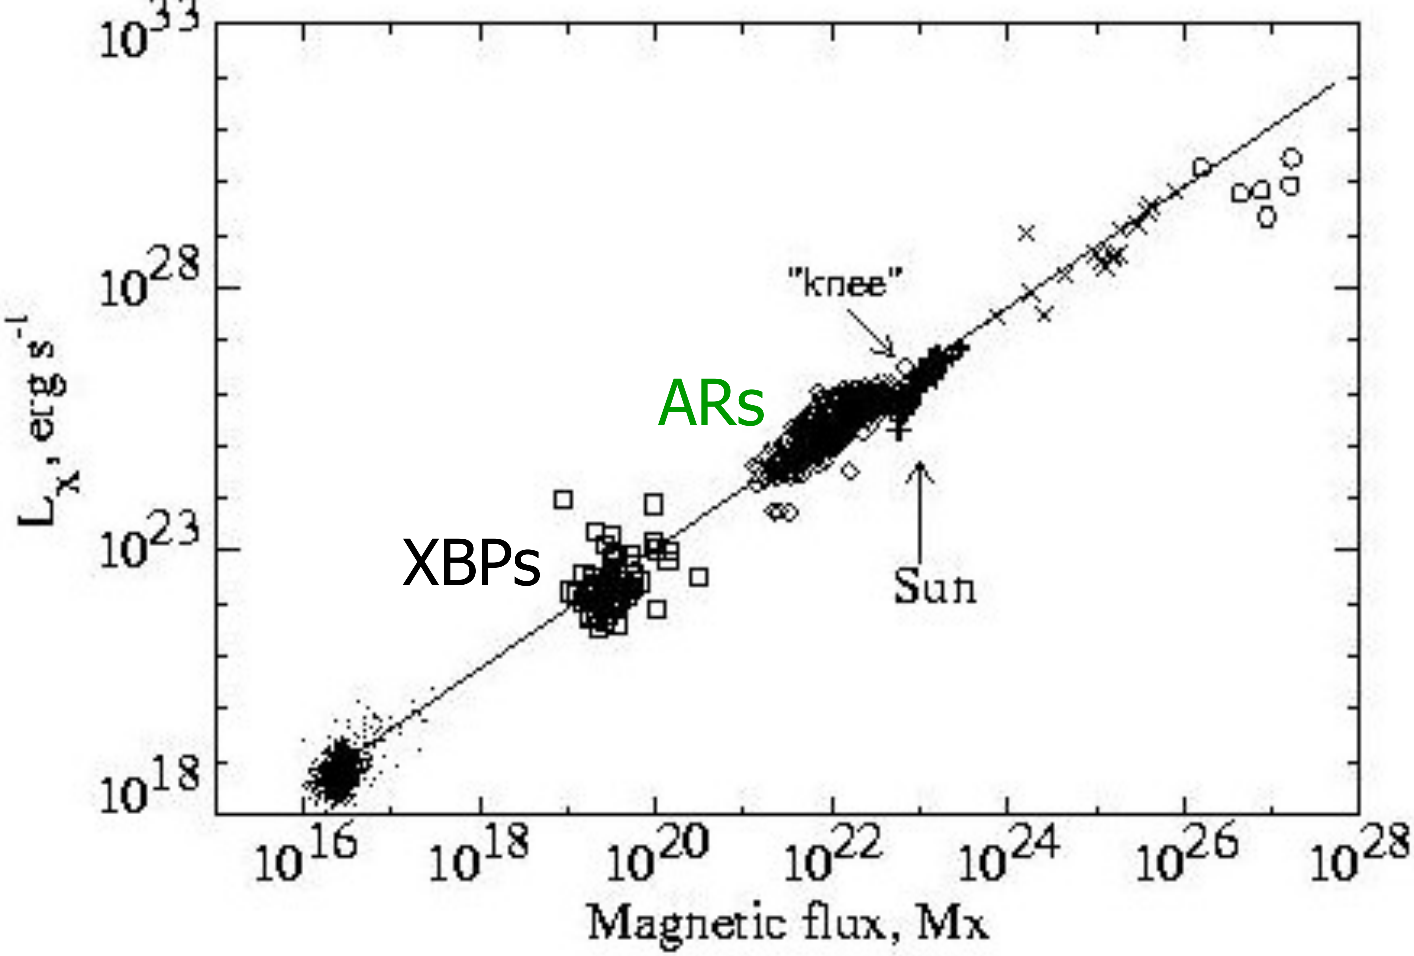
Vernazza *et al.* 1981



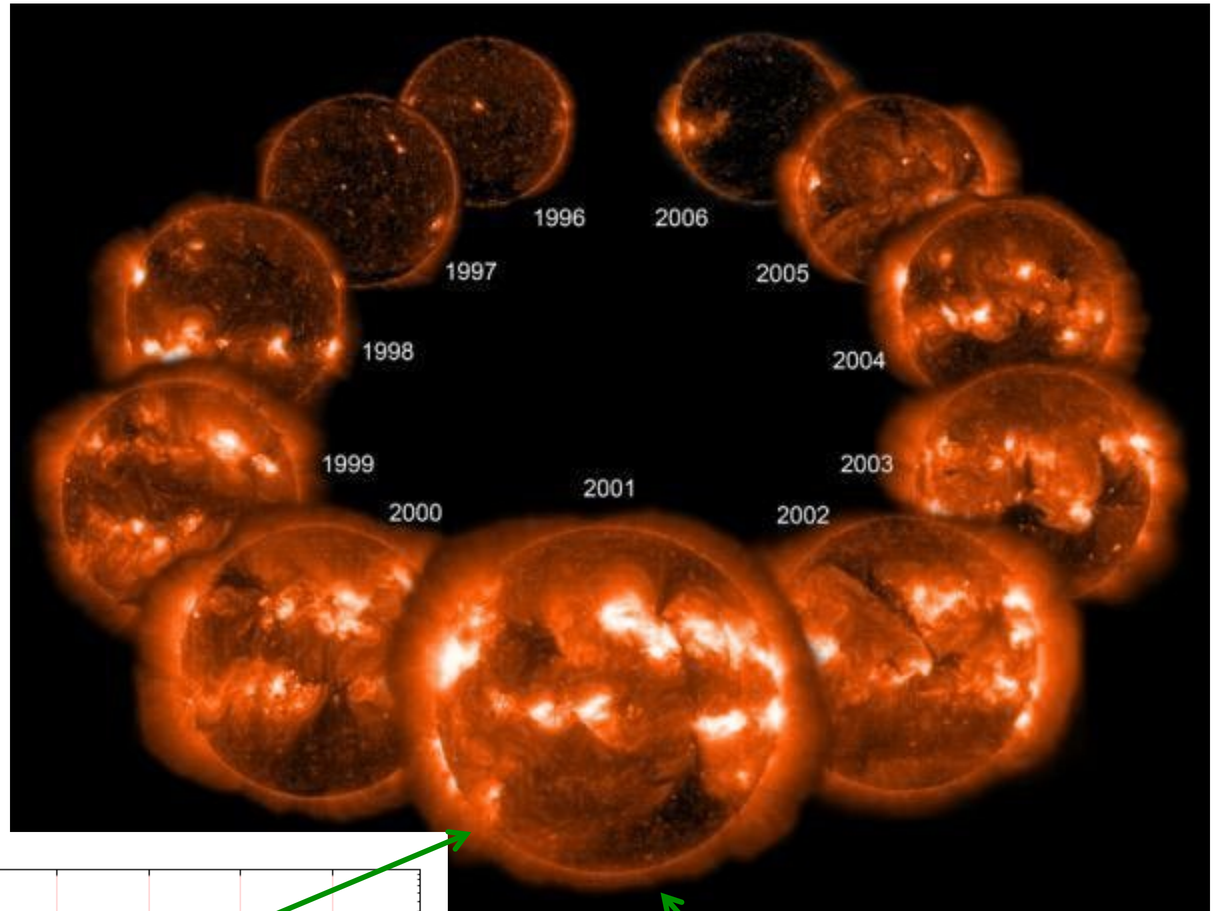
- Radiation: not optically thin
- Ionization level varies with T

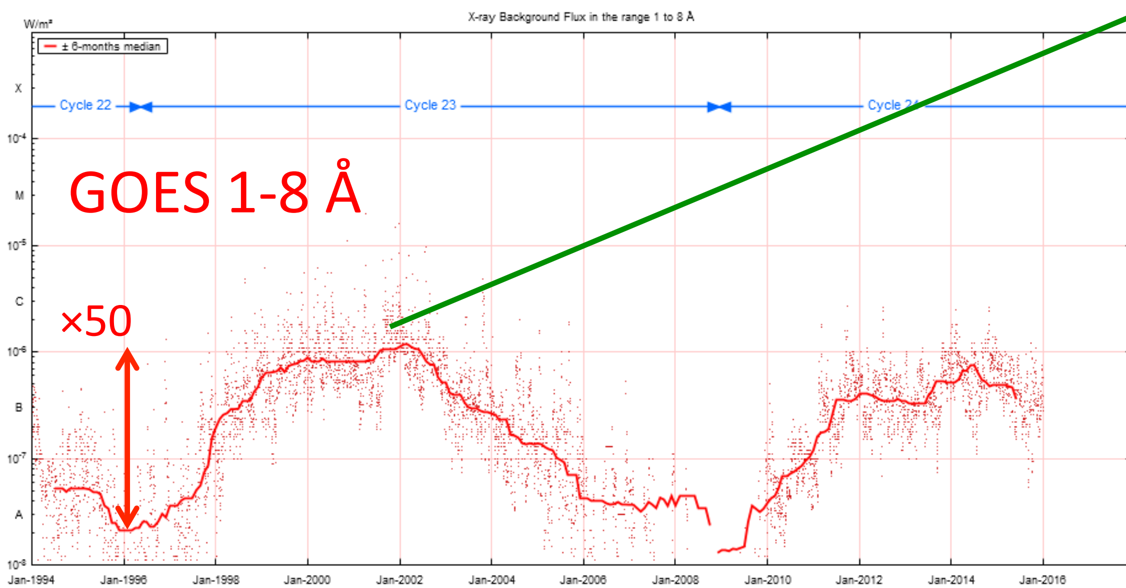
# Heating is Magnetic

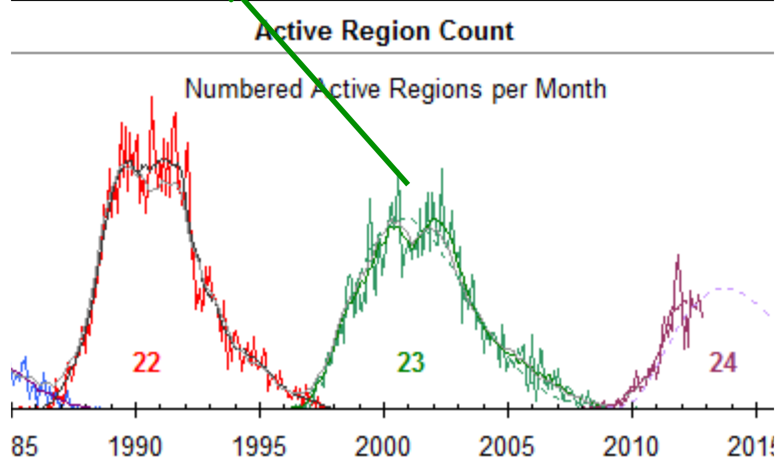
Pevtsov et al. 2003



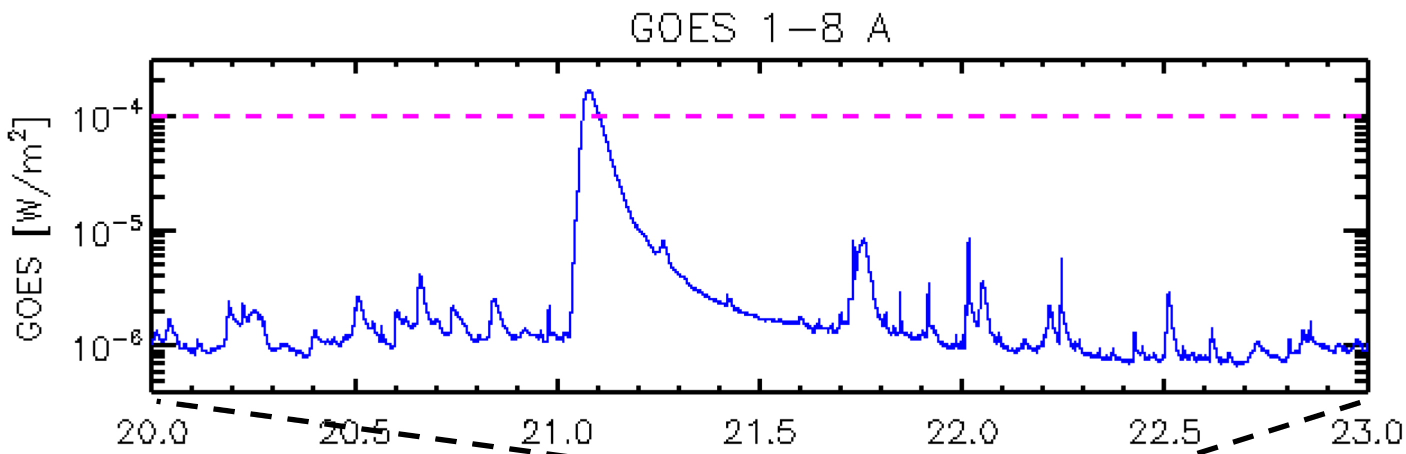
# Field varies – corona varies

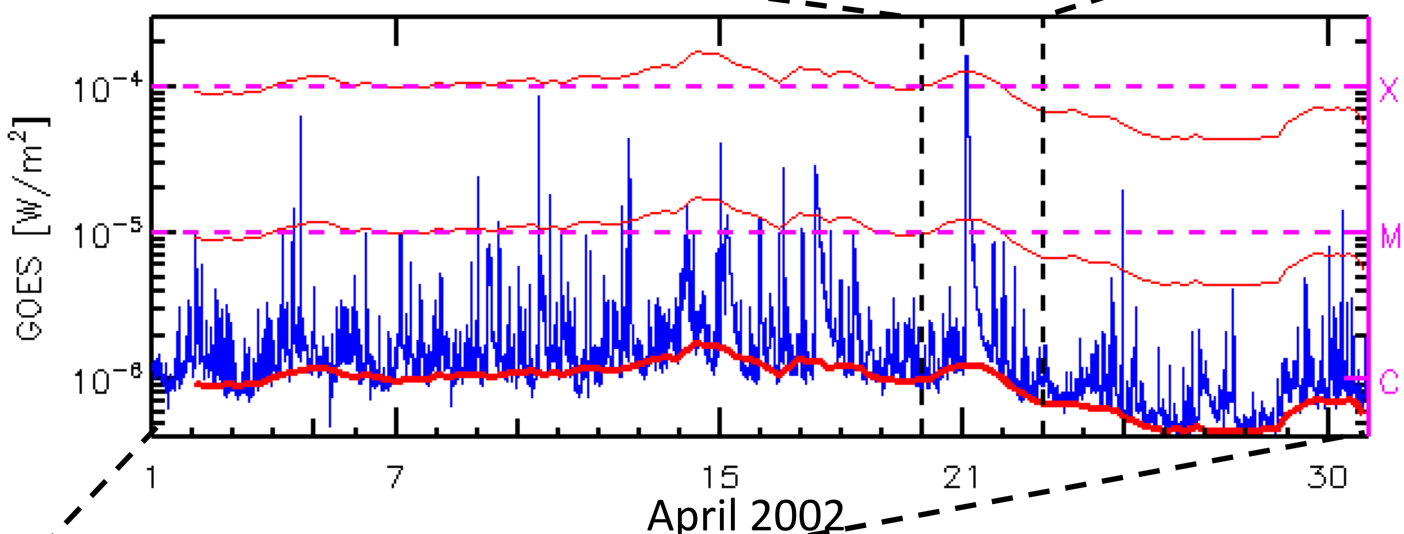


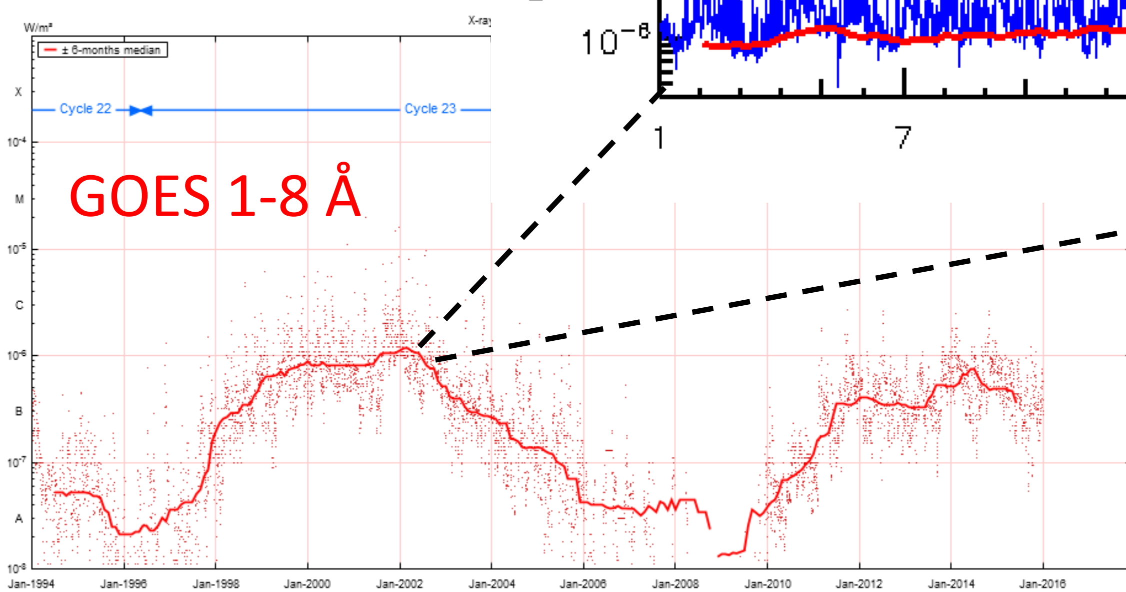




X-rays: highly variable – flares

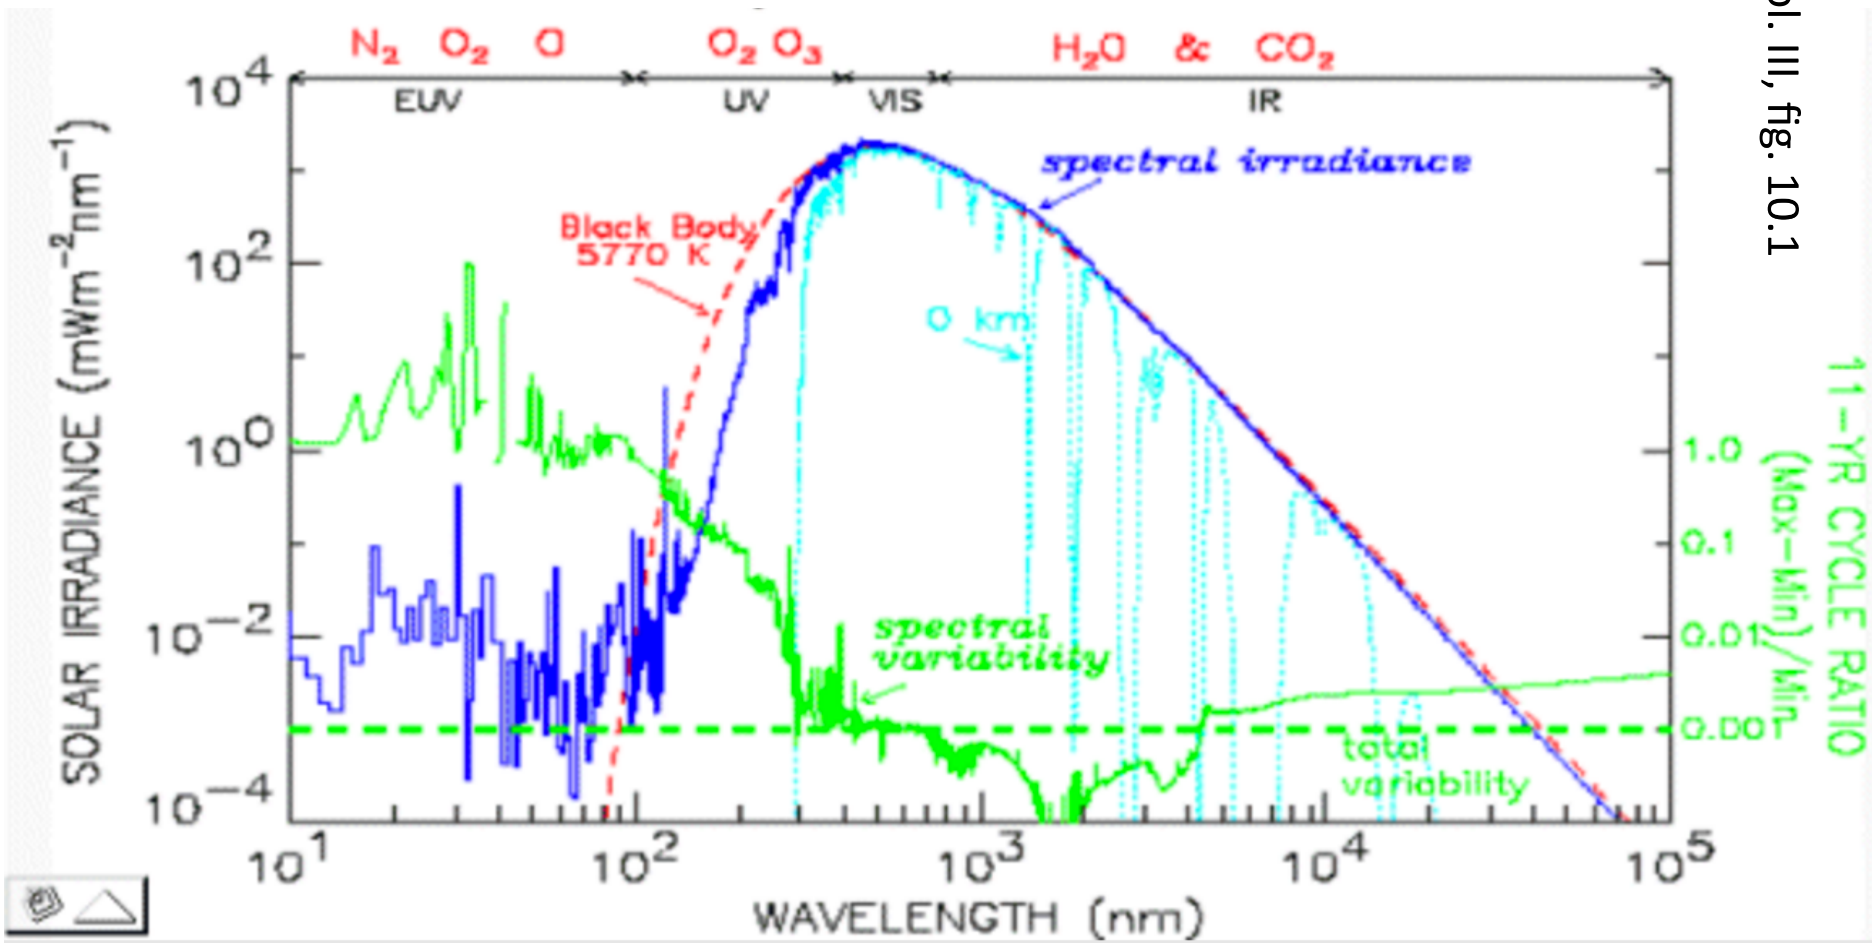






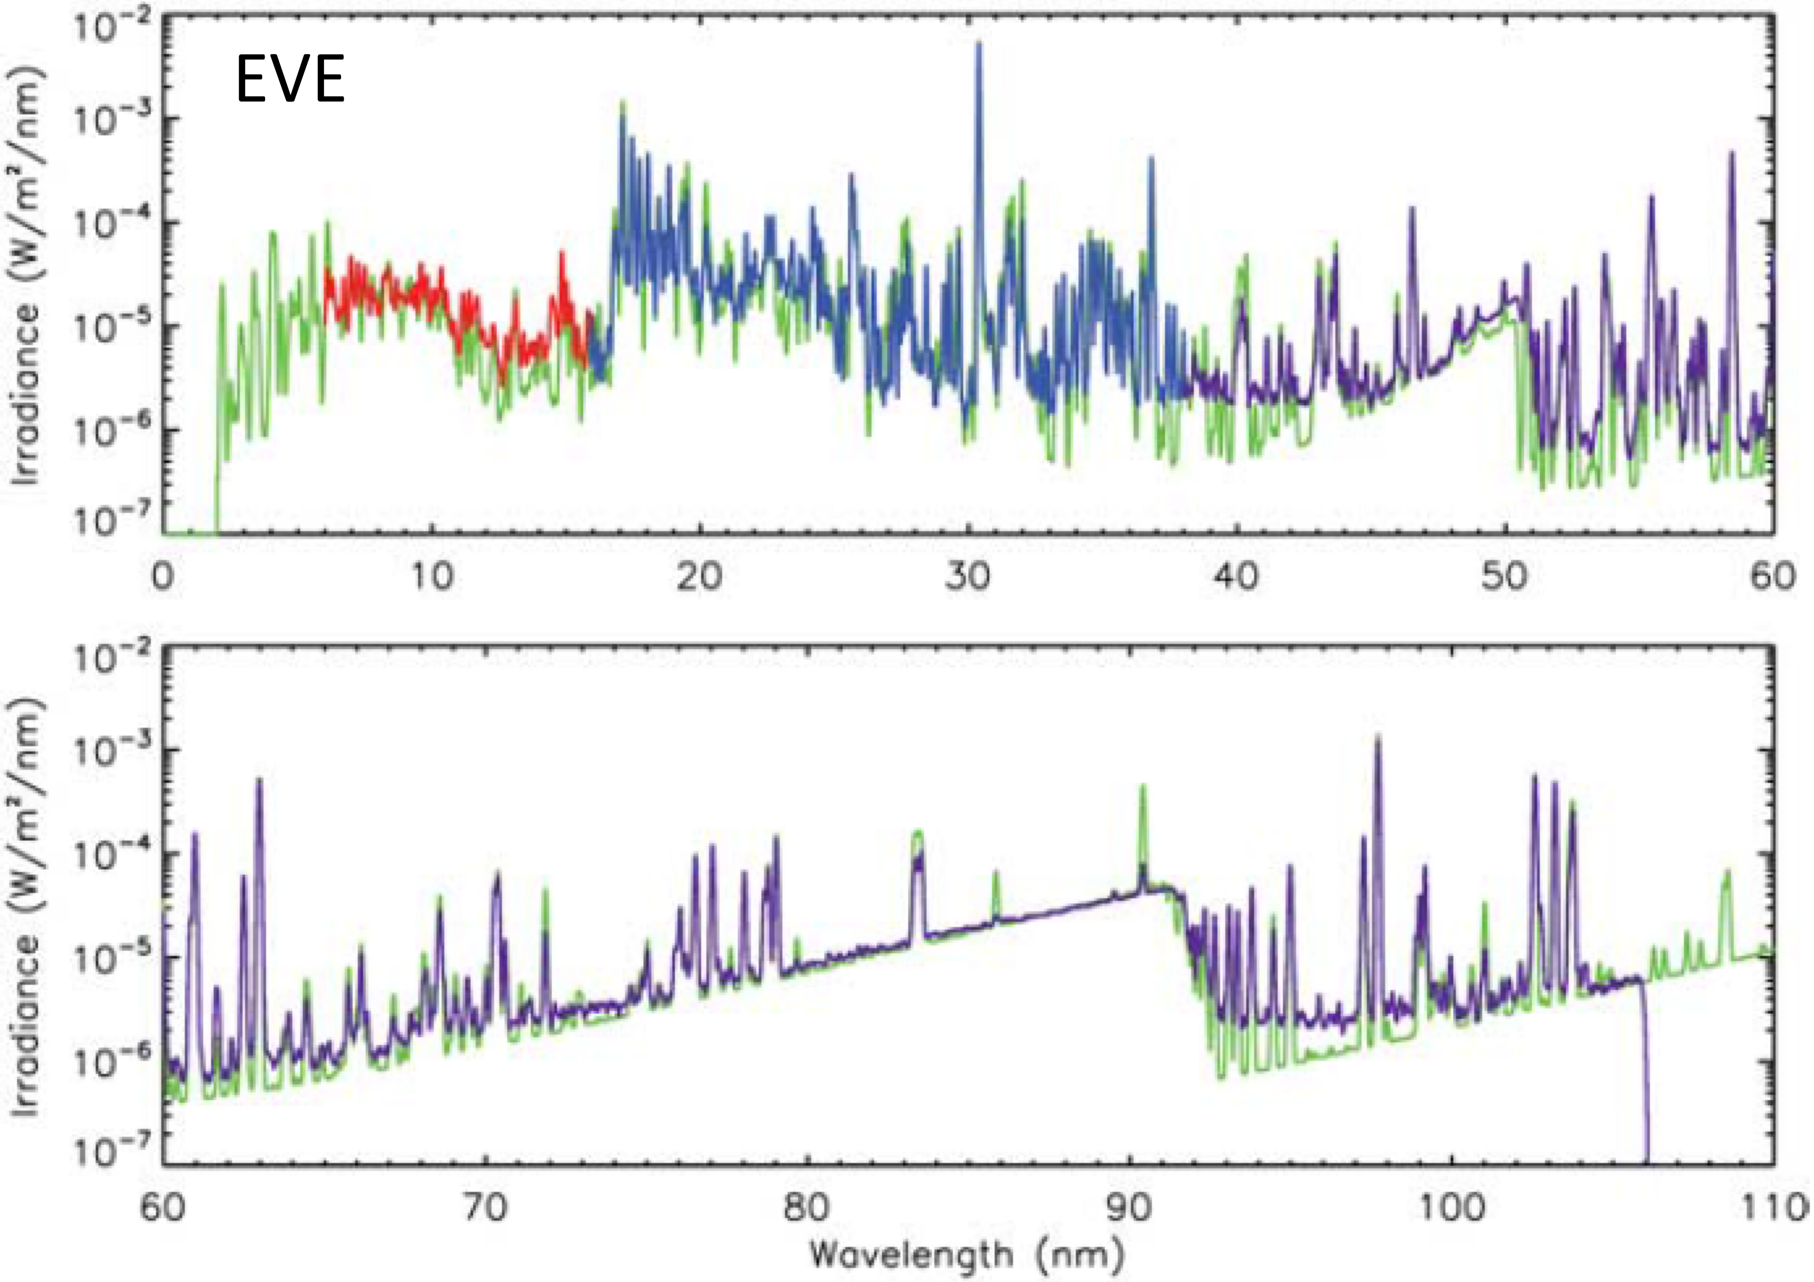
do smaller flares heat the corona?

# Corona produces EUV & X-ray

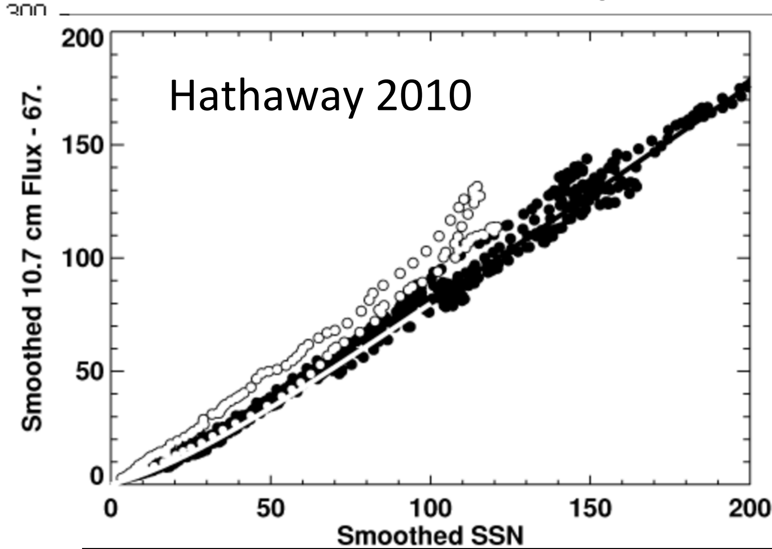


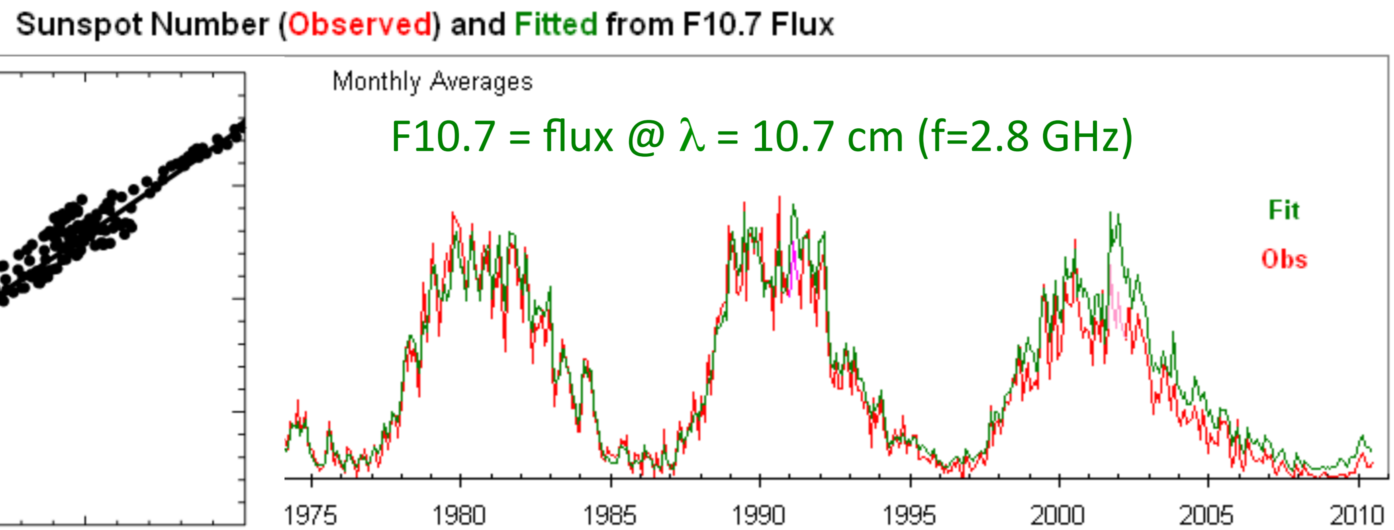
Vol. III, fig. 10.1

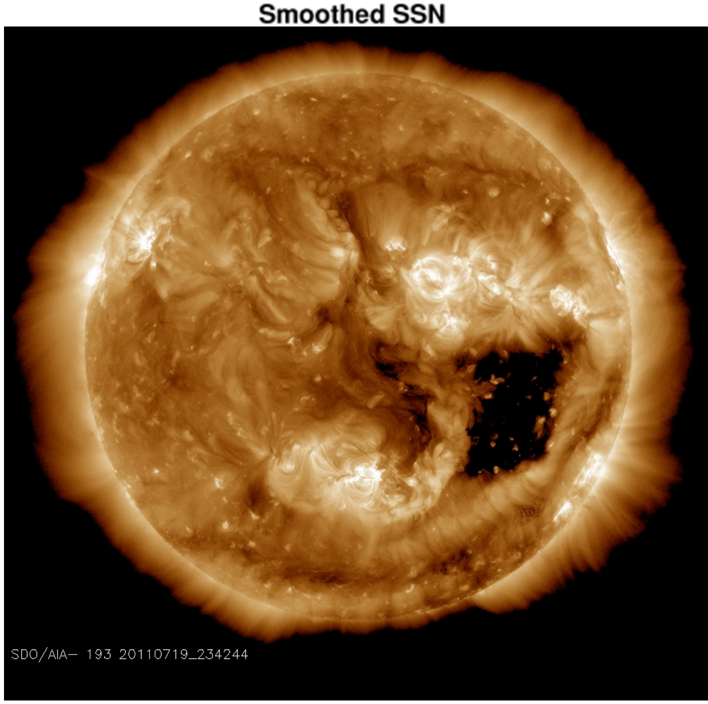
Chamberlin *et al.* 2009

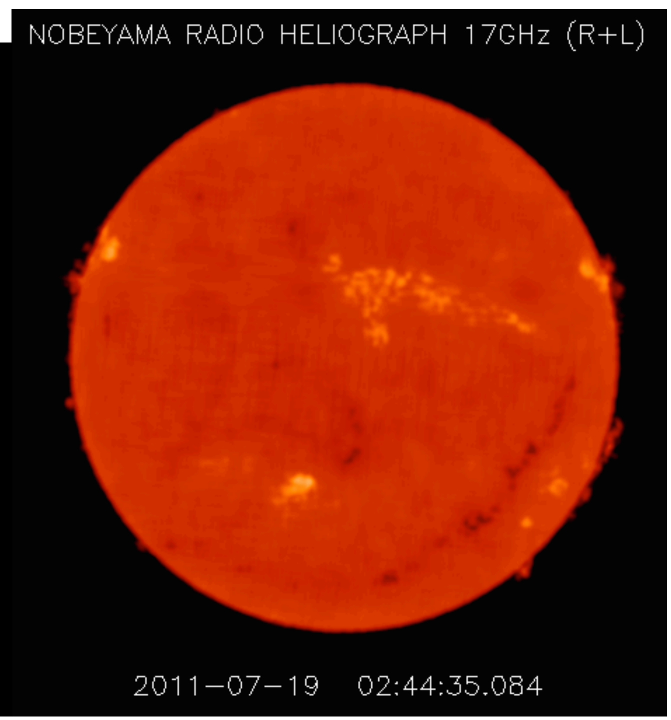


# Corona produces μ-waves

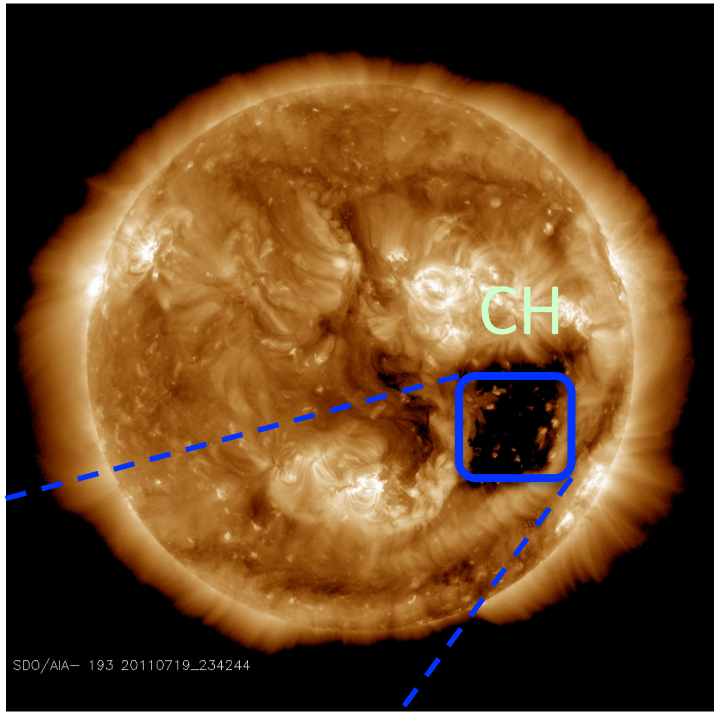




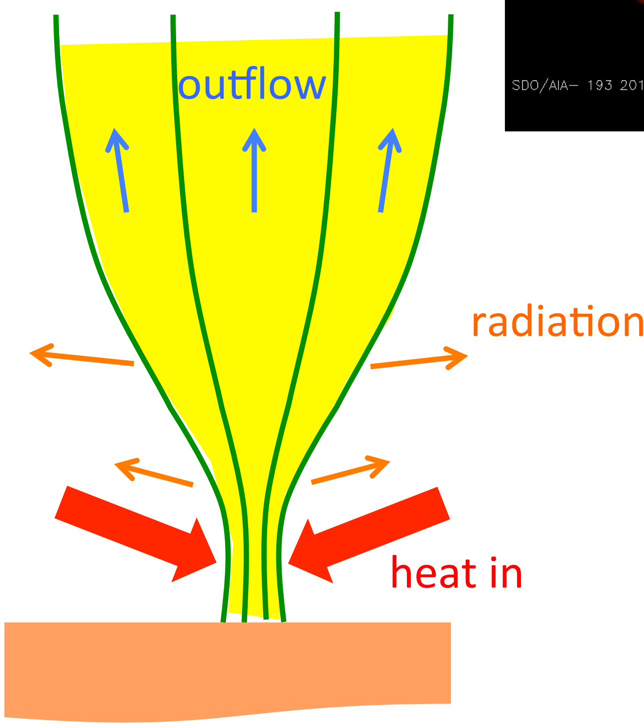




**B** large enough to restrict plasma motion: only along field lines



Wind: from open flux



specific enthalpy

$$w(\rho) \propto \frac{\gamma}{\gamma - 1} \rho^{\gamma - 1}$$

Advective energy loss –

$$\tfrac{1}{2} \rho \mathbf{v} v^2 + \rho \mathbf{v} w(\rho)$$

>> radiative loss

Bernoulli's law: $\dfrac{Q}{\dot{M}} = \text{const.}$

Energy loss = $A\rho v\left[\frac{1}{2}v^2 + w(\rho) + \Psi(s)\right]$ = Q = fixed & given

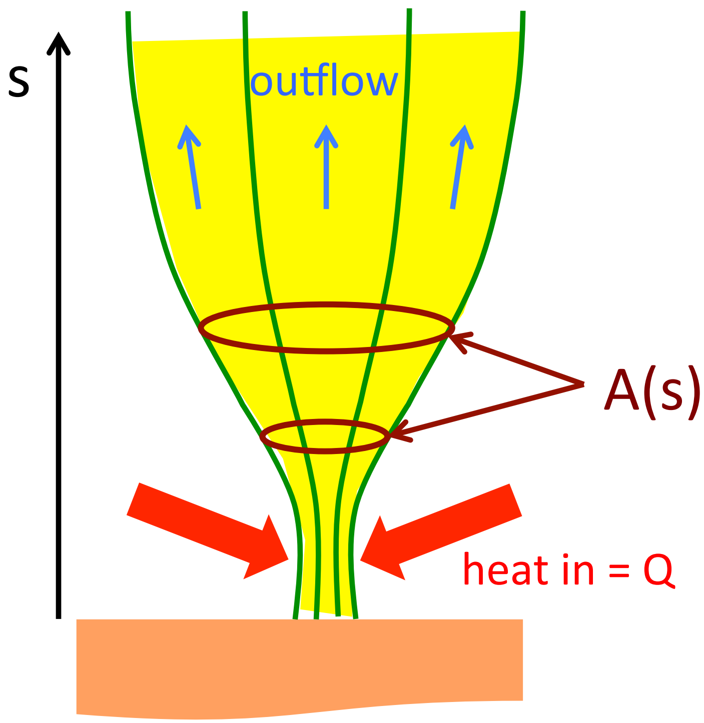
mass loss fixed & unknown

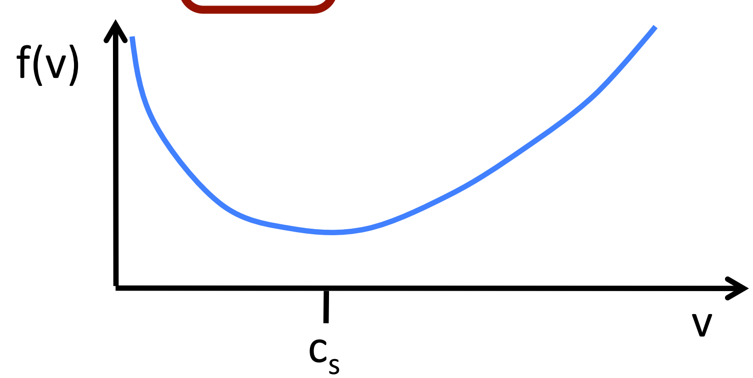
Simple case: Isothermal … $\gamma \to 1$

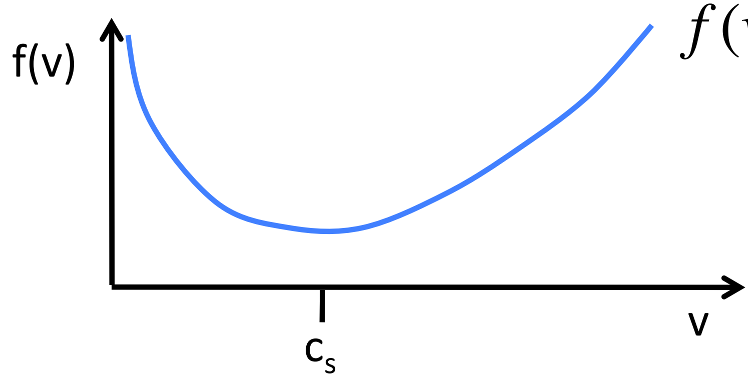
$$w(\rho) \propto \frac{\gamma}{\gamma - 1}\rho^{\gamma-1} \rightarrow c_s^2 \ln(\rho) + \text{const.}$$

$$\rightarrow \frac{1}{2}v^2 - c_s^2 \ln(v) - c_s^2 \ln[A(s)] + \Psi(s) = \text{const.}$$

$$= f(v) + g(s) = \text{const.}$$







$$f(v) = \tfrac{1}{2}v^2 - c_s^2 \ln(v)$$

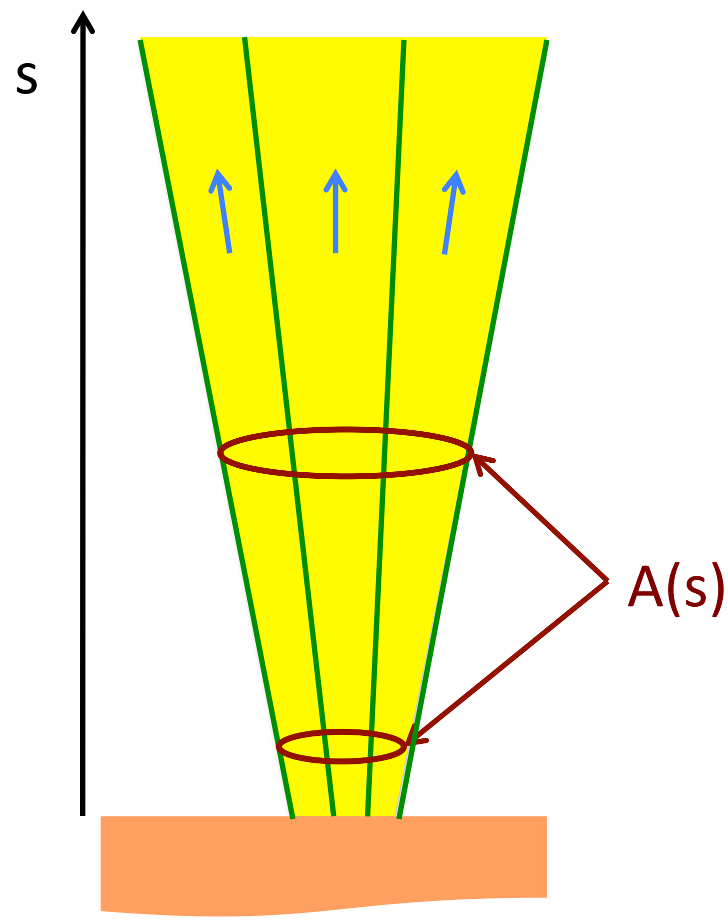
$$g(s) = -c_s^2 \ln[A(s)] - \frac{R_o v_{\text{esc}}^2}{2r(s)}$$

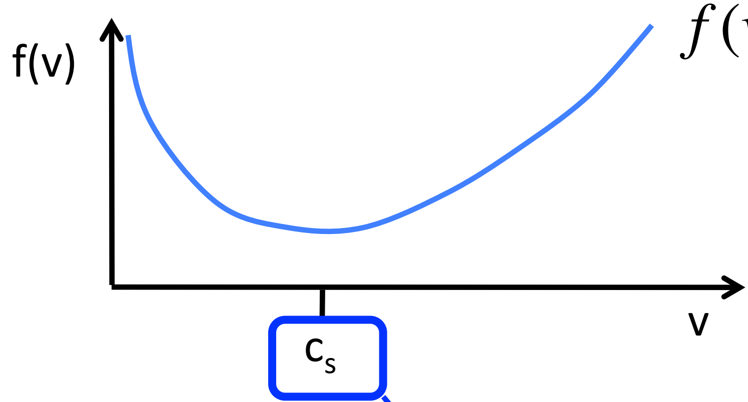
tube:

cone w/ vertical axis

$A(s) \sim s^2$ $\quad$ $s = r$

$$g(r) = -2c_s^2 \ln(r) - \frac{R_o v_{\text{esc}}^2}{2r}$$





$$f(v) = \tfrac{1}{2}v^2 - c_s^2 \ln(v)$$

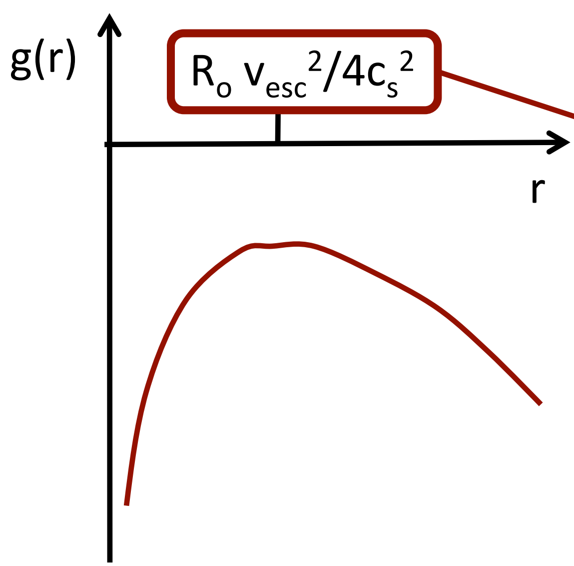
$$F(v,r) = f(v) + g(r) = \frac{Q}{\dot{M}} = \text{const.}$$

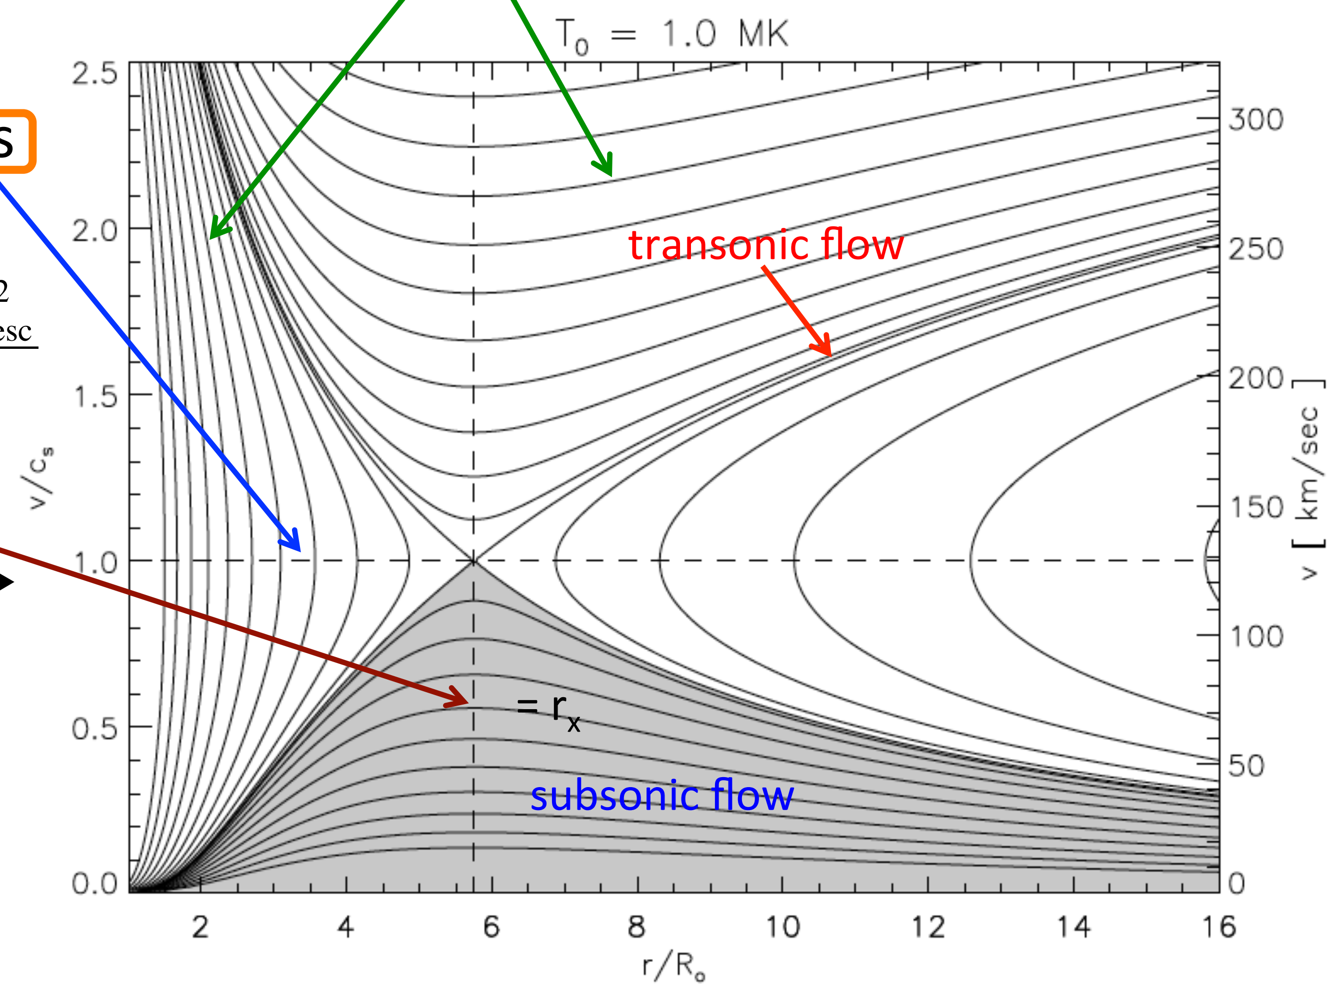
tube:

cone w/ vertical axis

$A(s) \sim s^2$ $s = r$

$$g(r) = -2c_s^2 \ln(r) - \frac{R_o v_{esc}^2}{2r}$$





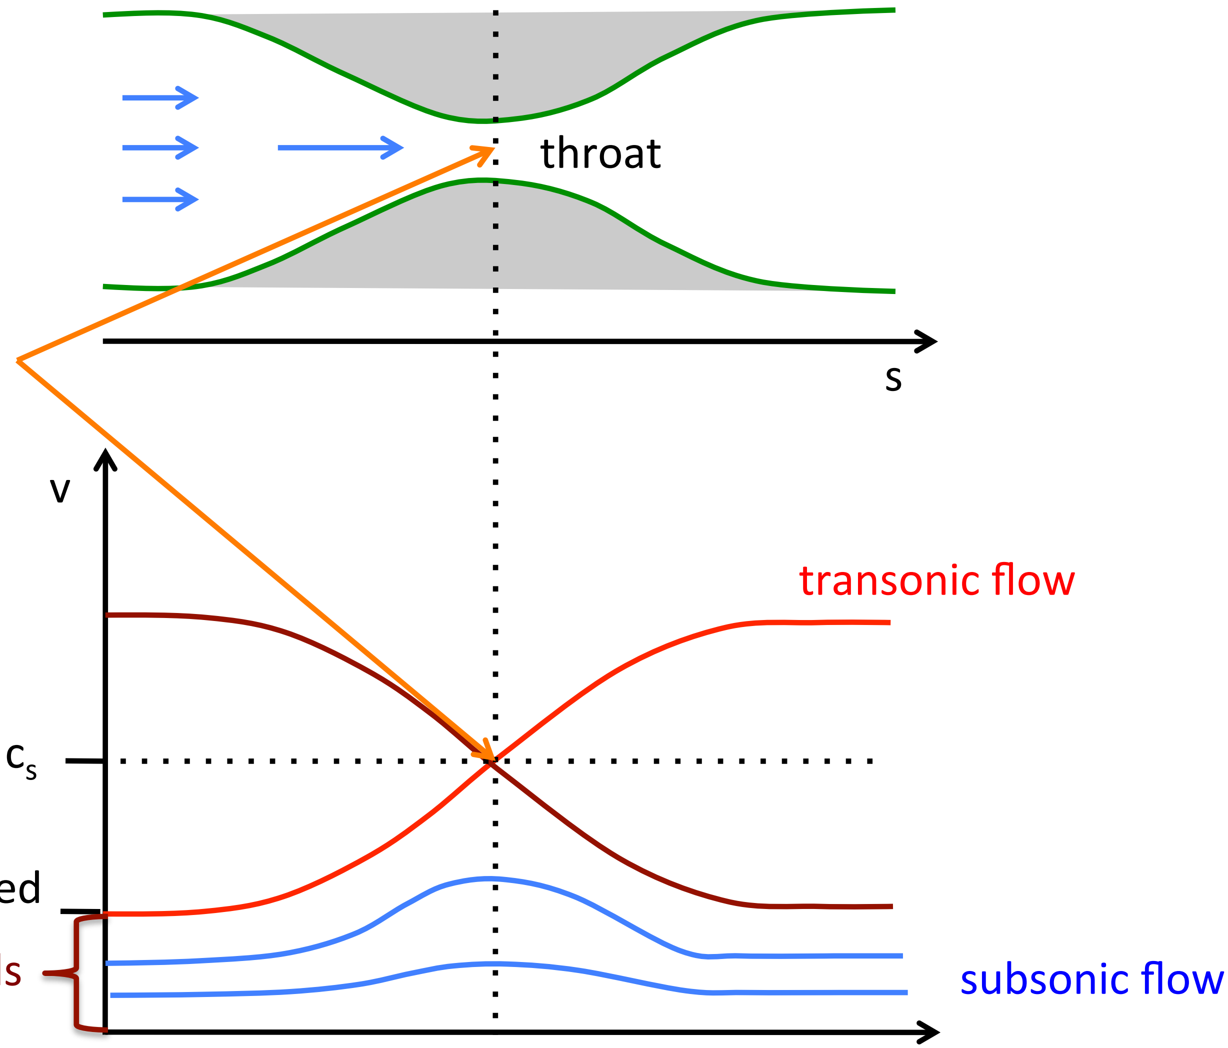
$$g(s) = -c_s^2 \ln[A(s)] + \Psi(s)$$

tube:

horizontal nozzle

$\Psi(s)$ = const.

$$g(s) = -c_s^2 \ln[A(s)]$$



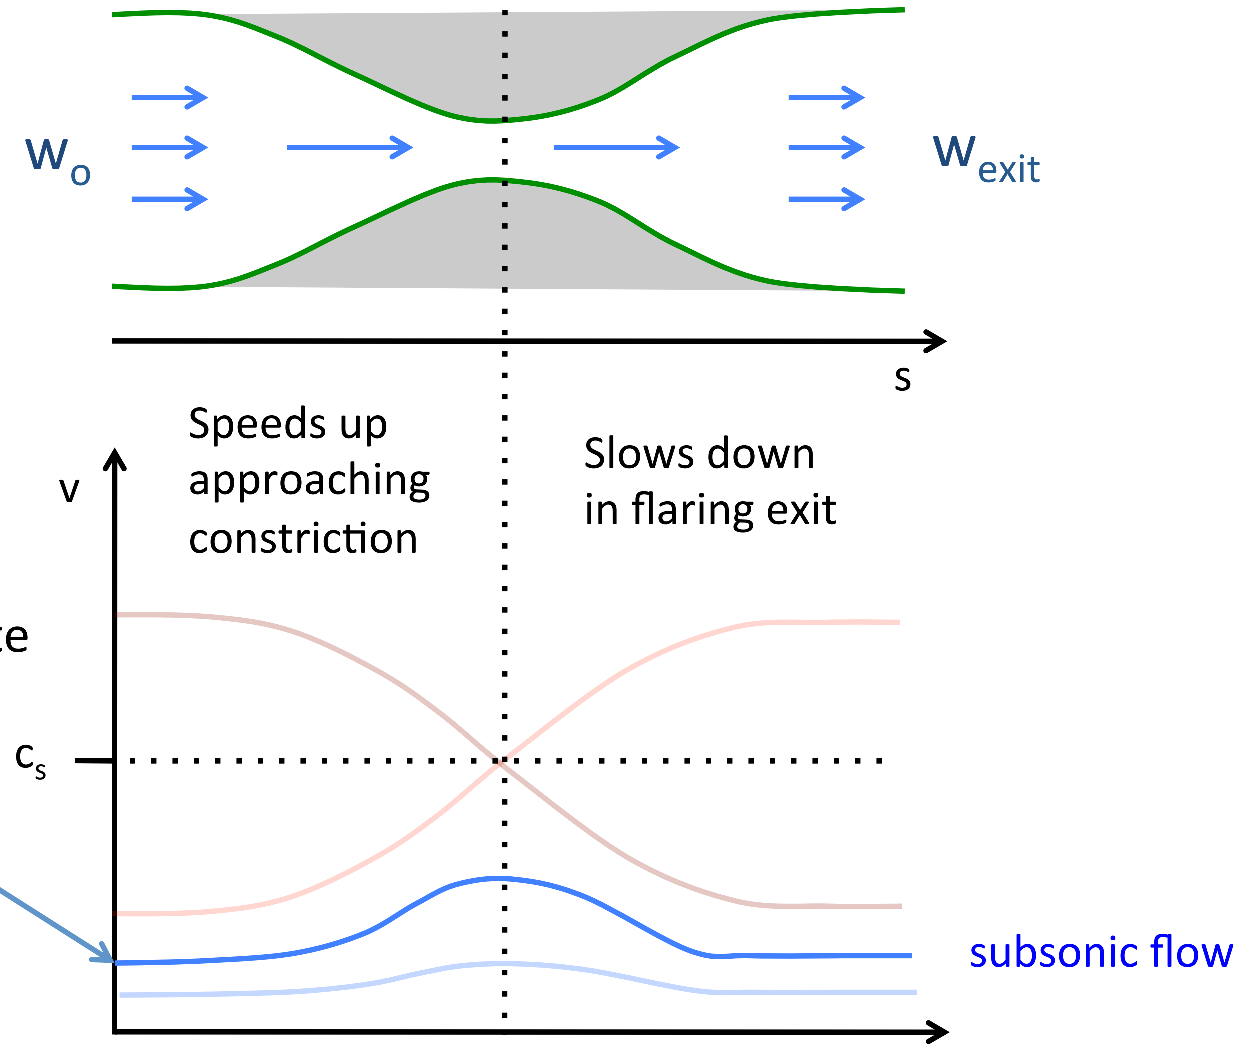
$$g(s) = -c_s^2 \ln[A(s)] + \Psi(s)$$

tube:

horizontal nozzle

$\Psi(s)$ = const.

$$g(s) = -c_s^2 \ln[A(s)]$$



Inflow = mass loss rate

set by back-pressure

$W_{exit}$

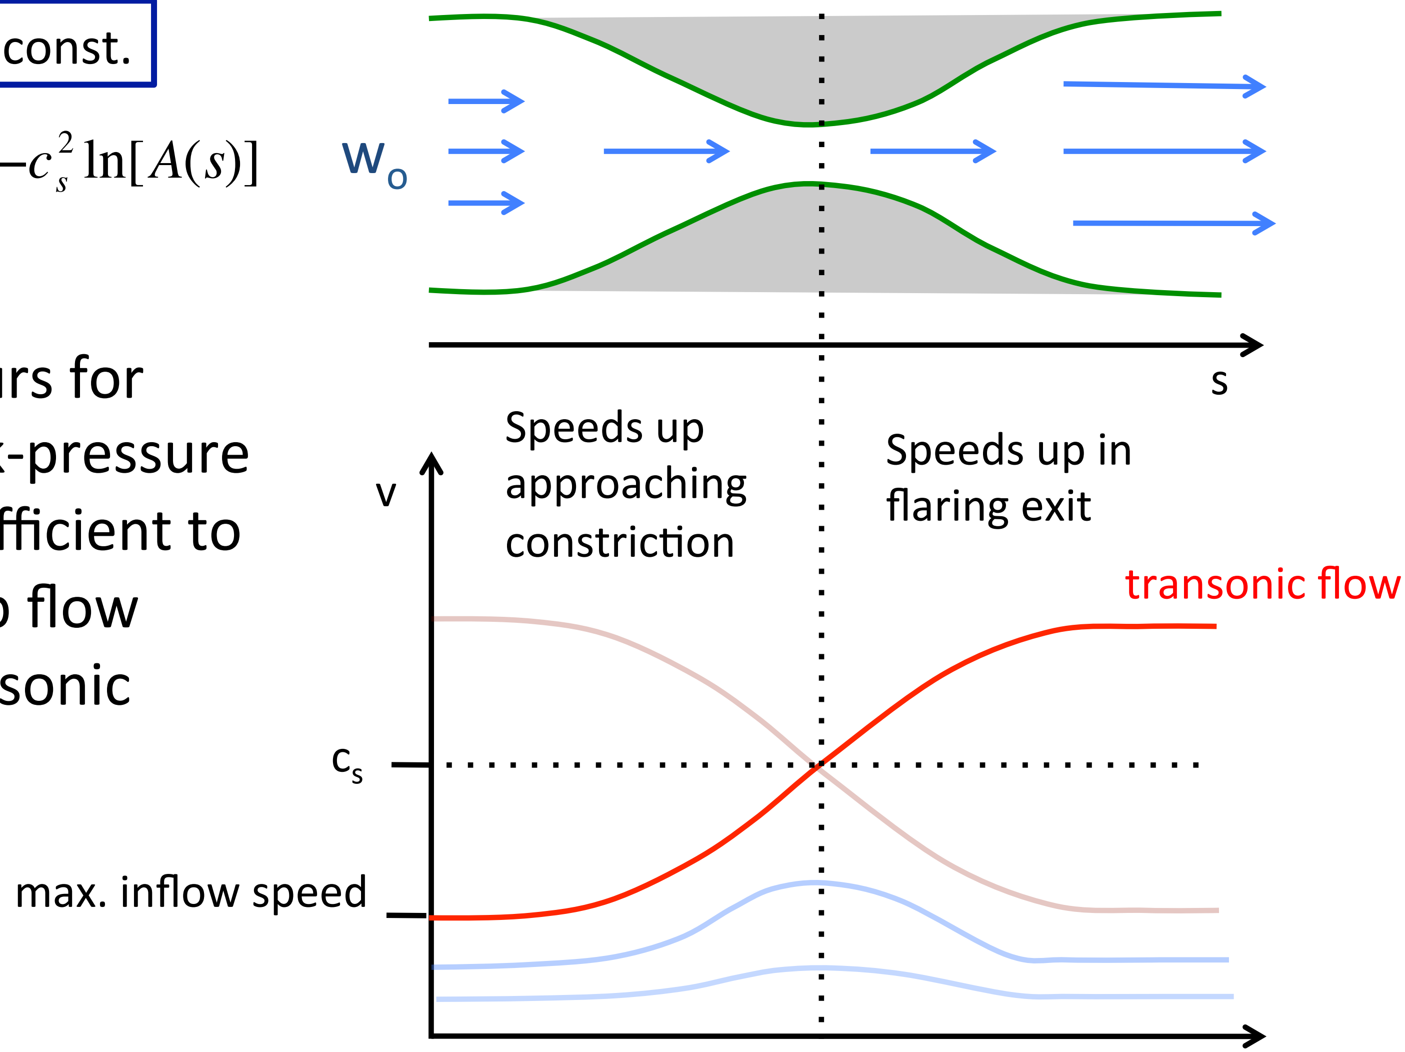
tube:

horizontal nozzle

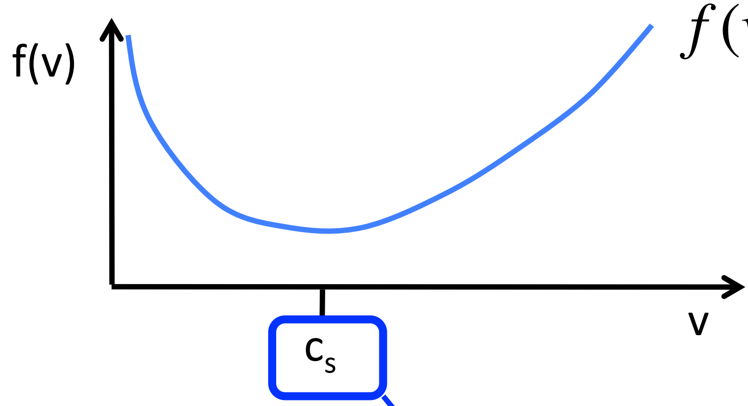
$\Psi(s)$ = const.

$$g(s) = -c_s^2 \ln[A(s)]$$

$$g(s) = -c_s^2 \ln[A(s)] + \Psi(s)$$



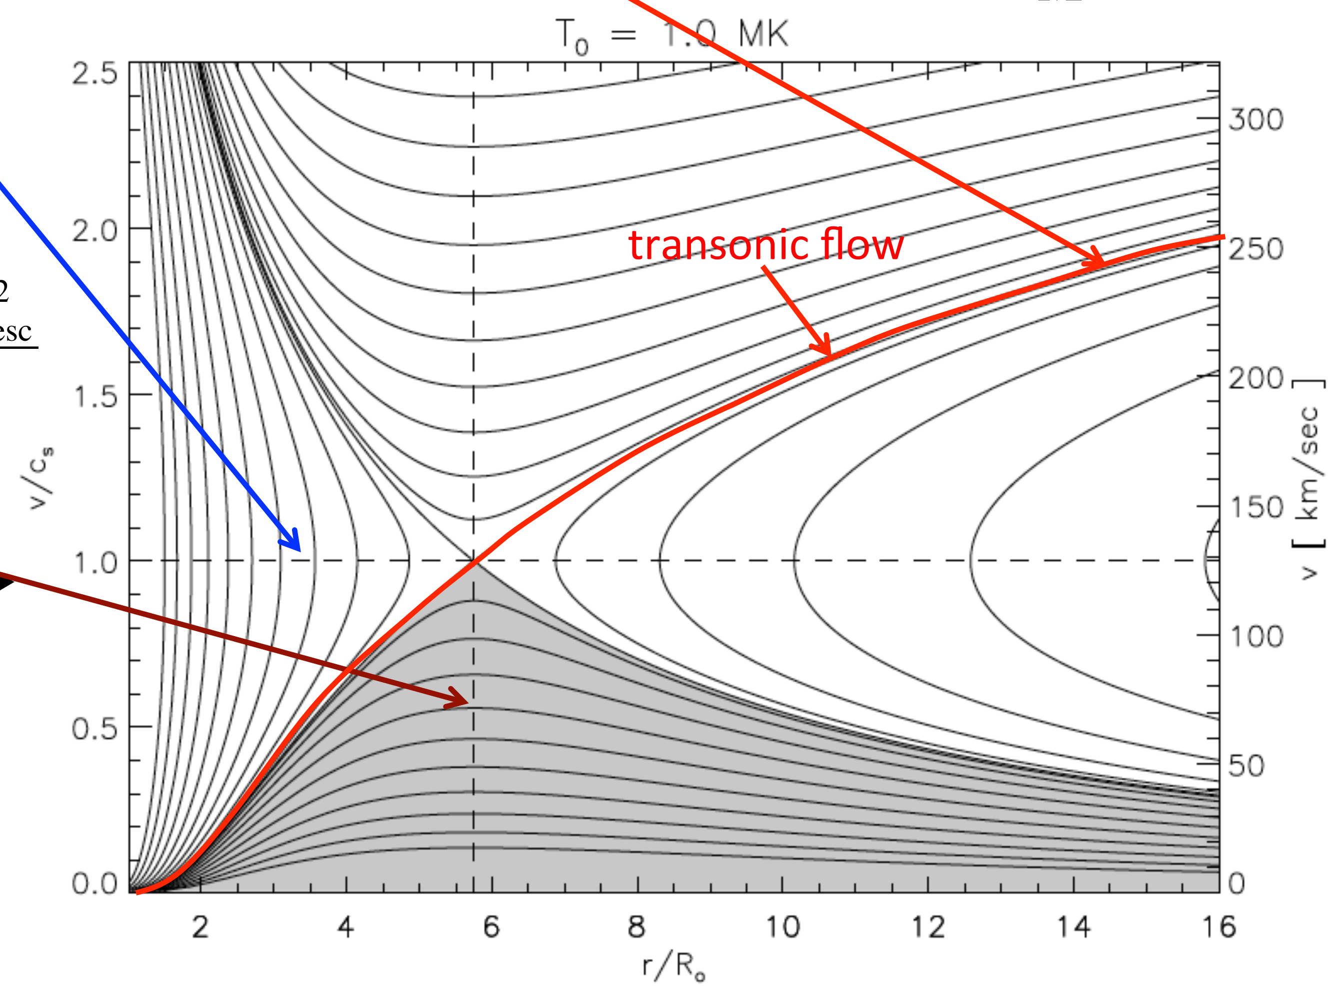
occurs for back-pressure insufficient to keep flow sub-sonic



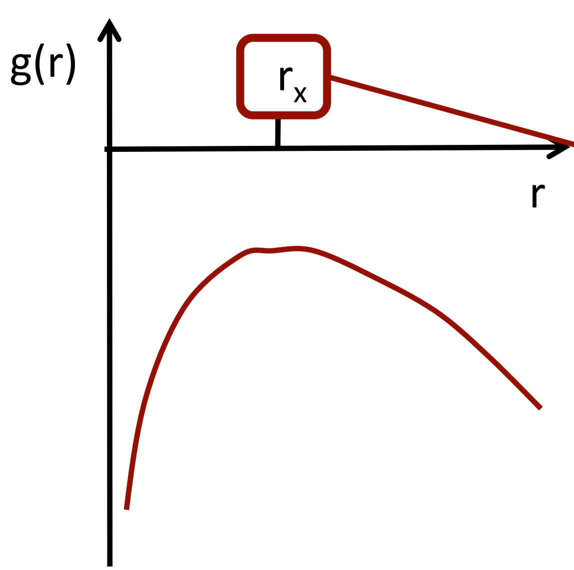
$$f(v) = \tfrac{1}{2}v^2 - c_s^2 \ln(v)$$

const. fixed by need to become transonic when external back-pressure is insufficient – i.e. vacuum around sun

$$F_x = f(c_s) + g(r_x) = \frac{Q}{\dot{M}}$$



$$g(r) = -2c_s^2 \ln(r) - \frac{R_o v_{\rm esc}^2}{2r}$$



➔ Mass loss rate is set by heating rate*

$$\dot{M} = \frac{Q}{F_x}$$

➔ density everywhere is set by mass loss rate

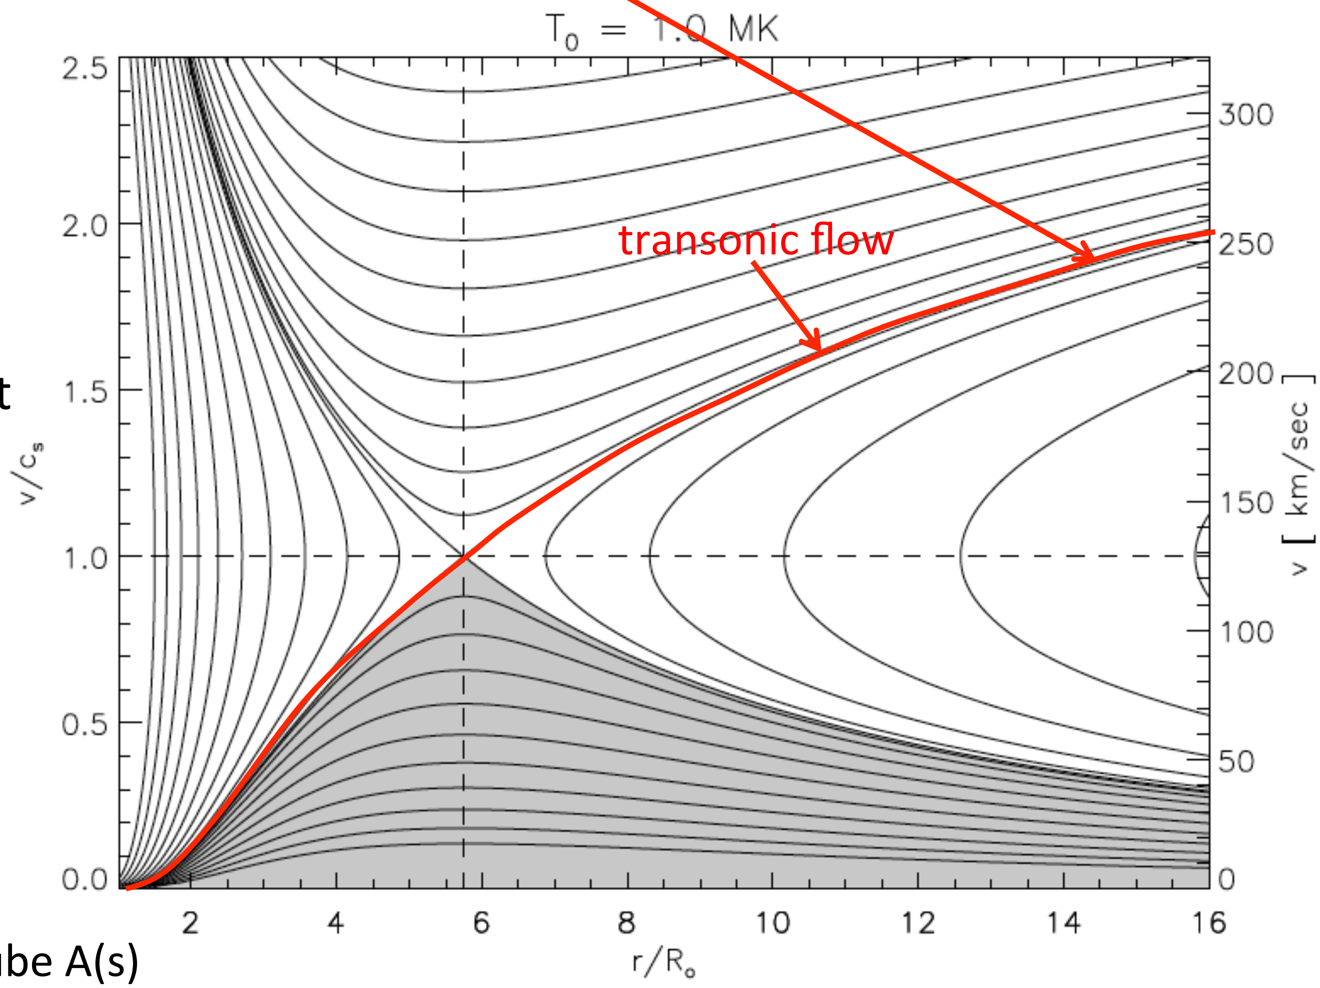
$$\rho(r_x) = \frac{\dot{M}}{A(r_x)c_s}$$

➔ density @ base is set by heating rate*…

… and it will be lower than density on closed loops w/ same heating (Why?)

const. fixed by need to become transonic when external back-pressure is insufficient – i.e. vacuum around sun

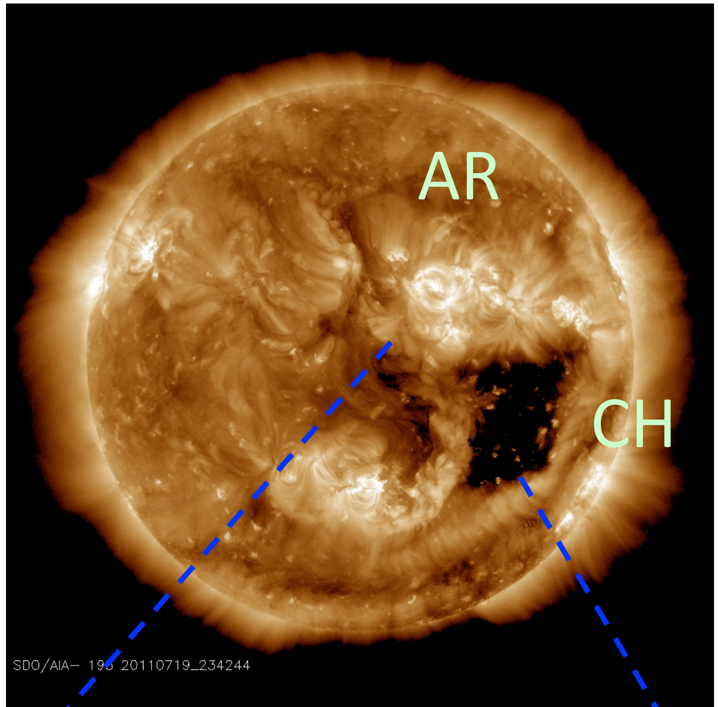
$$F_x = f(c_s) + g(r_x) = \frac{Q}{\dot{M}}$$

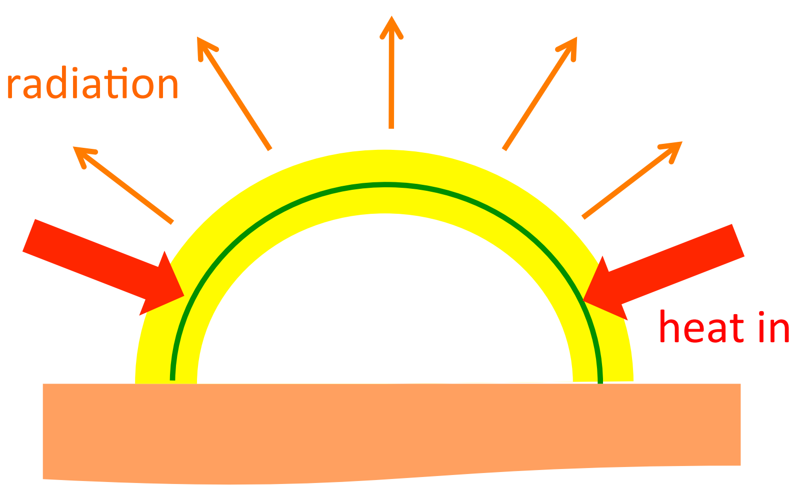


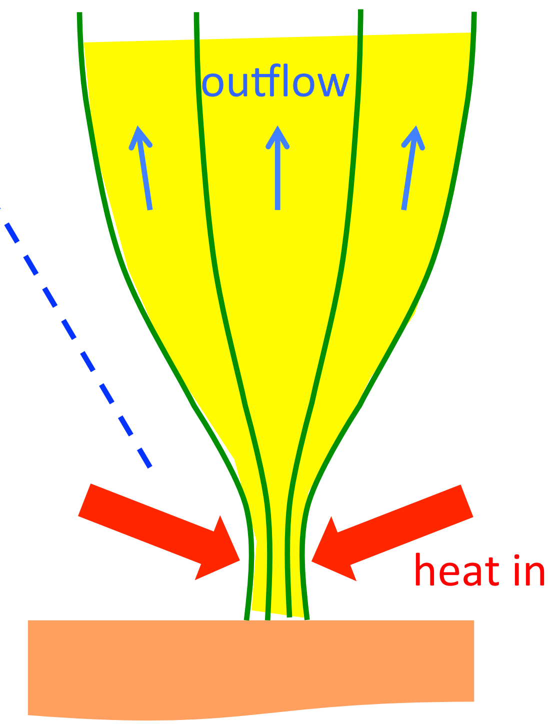
* … and geometry of flux tube A(s)

**B** large enough to restrict plasma motion: only along field lines

Different coronae from different magnetic topology: open vs. closed







# Why are some field lines open & others closed?

Magnetic field dominates:
nothing capable of countering its force so…

$$(\nabla \times \mathbf{B}) \times \mathbf{B} = 0$$

$$\Rightarrow \boxed{\nabla \times \mathbf{B} = \alpha \mathbf{B}} \quad (i.e. \parallel \mathbf{B})$$

simplest version: $\alpha = 0$ (by fiat)

$$\Rightarrow \nabla \times \mathbf{B} = 0 \quad \Rightarrow \boxed{\mathbf{B} = -\nabla \chi}$$

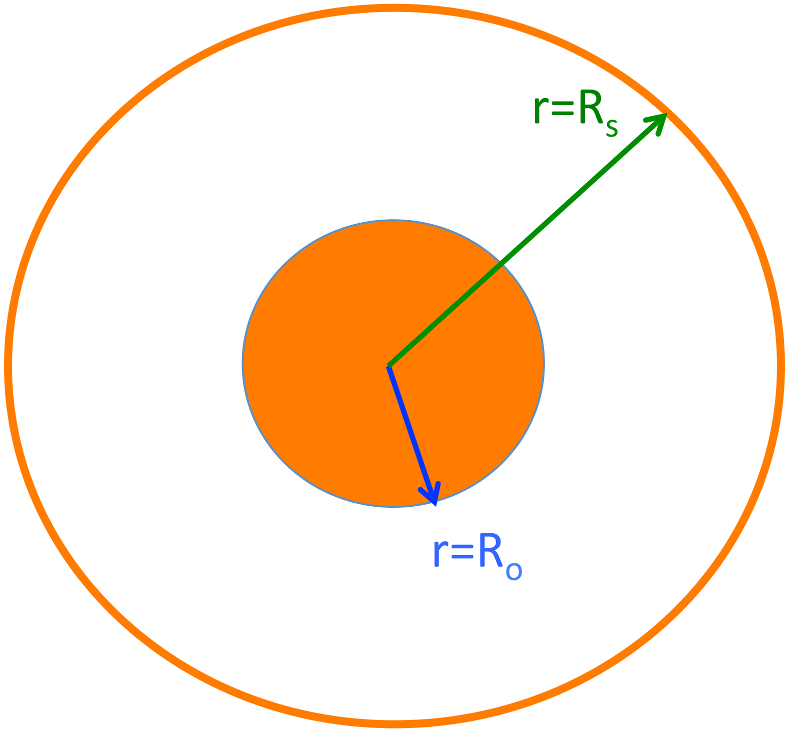
potential field
(cf. electrostatics)

$$\nabla \cdot \mathbf{B} = 0 \quad \Rightarrow \quad \nabla^2 \chi = 0$$

harmonic potential
(cf. electrostatics in vacuum)

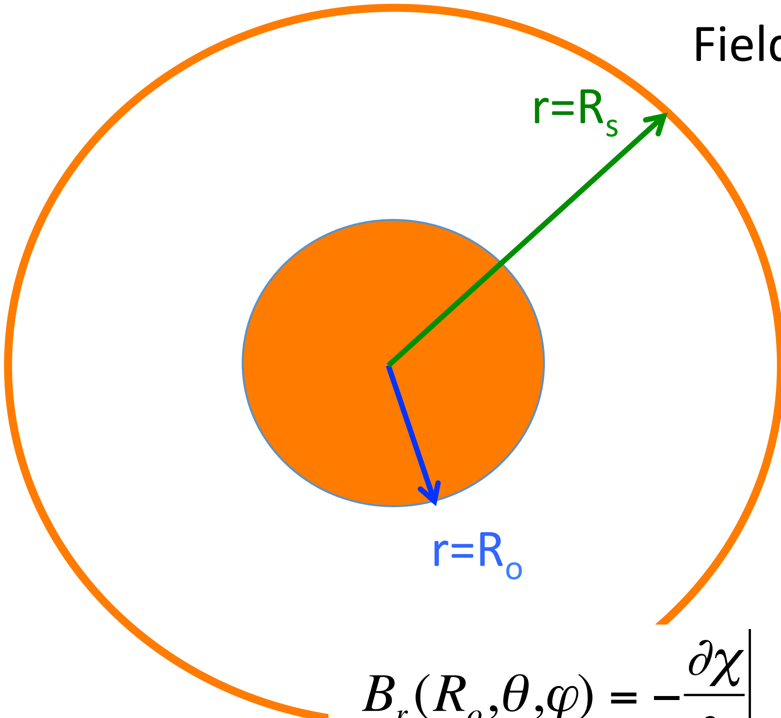
$$\mathbf{B} = -\nabla\chi \quad \& \quad \nabla^2\chi = 0$$

potential field outside sphere $r=R_o$



$$\mathbf{B} = -\nabla\chi \quad \& \quad \nabla^2\chi = 0$$

potential field outside sphere $r=R_o$



Field: purely radial @ $r=R_s$ (by fiat)

$$(B_\theta, B_\varphi) = 0 \quad \Rightarrow \quad \left(\frac{\partial\chi}{\partial\theta}, \frac{\partial\chi}{\partial\varphi}\right) = 0$$

$$\Rightarrow \quad \chi(R_s,\theta,\varphi) = 0$$ Dirichlet

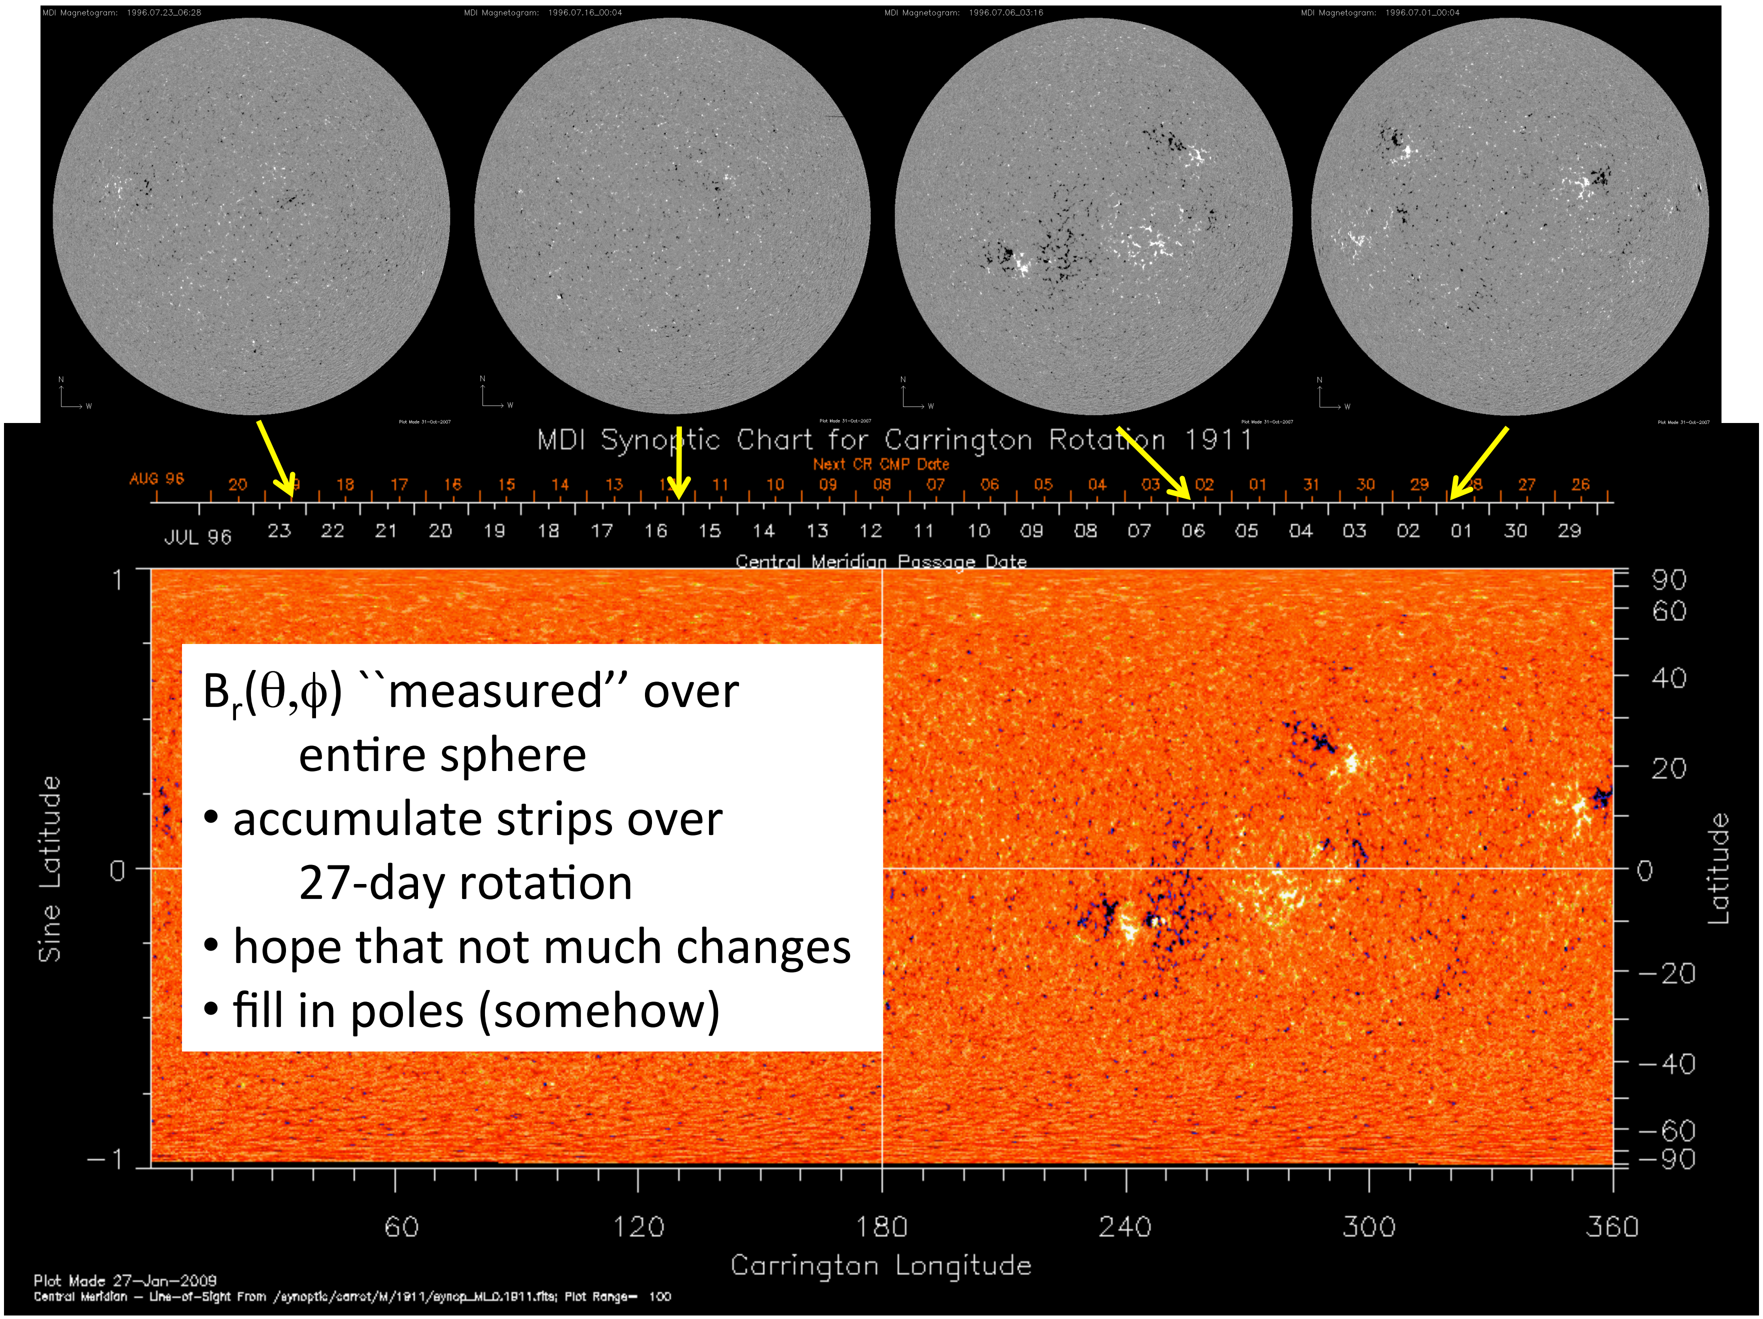
$$\chi(r,\theta,\varphi) = \sum_{\ell,m} A_{\ell,m}\left[\left(\frac{R_s}{r}\right)^{\ell+1} - \left(\frac{r}{R_s}\right)^{\ell}\right] Y_{\ell,m}(\theta,\varphi)$$

$$B_r(R_o,\theta,\varphi) = -\left.\frac{\partial\chi}{\partial r}\right|_{r=R_o}$$ Observed (Neumann)

$$B_r(R_o,\theta,\varphi) = \sum_{\ell,m} \frac{A_{\ell,m}}{R_s}\left[(\ell+1)\left(\frac{R_s}{R_o}\right)^{\ell+2} + \ell\left(\frac{R_o}{R_s}\right)^{\ell-1}\right] Y_{\ell,m}(\theta,\varphi)$$

- Observe $B_r(\theta,\phi)$ @ photosphere
- decompose w/ spherical harmonics
- coeffs. ➔ $A_{l,m}$

time



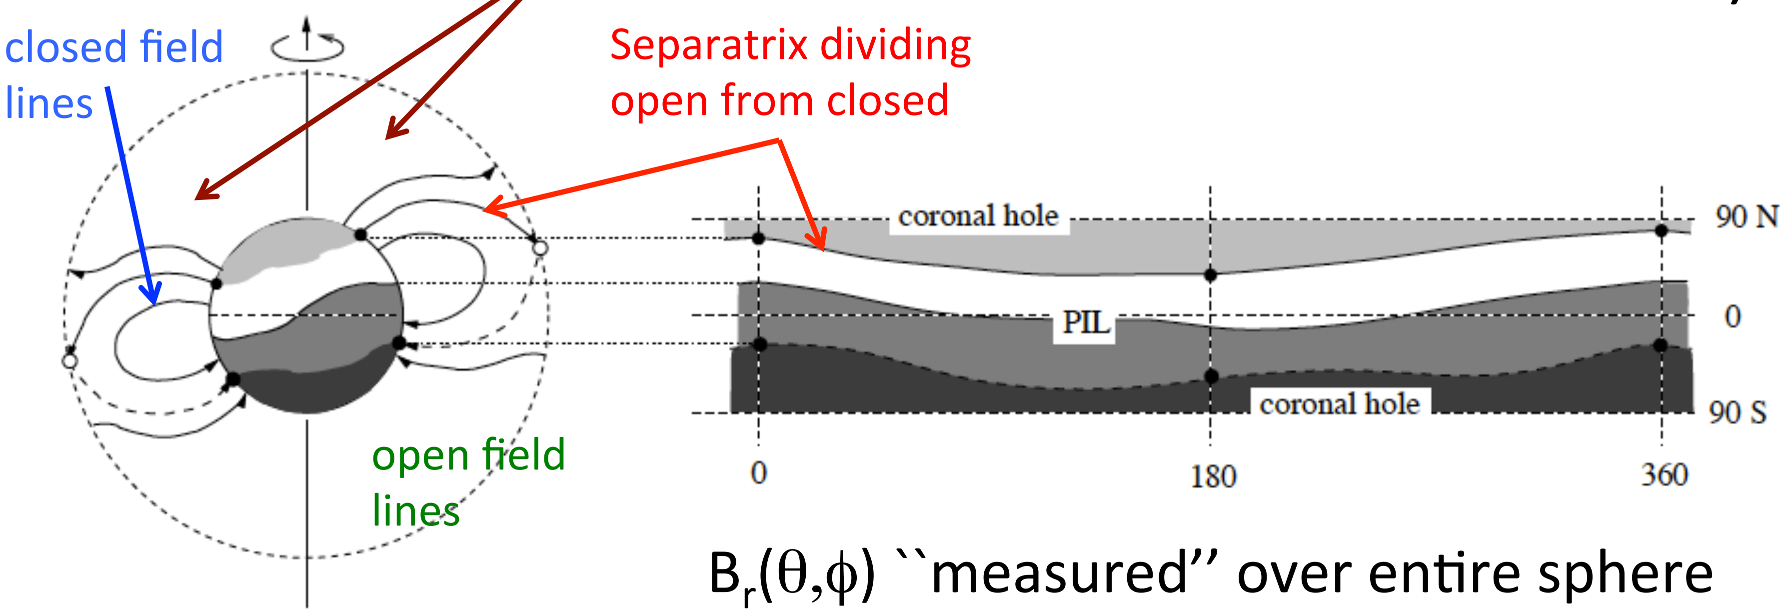
$B_r(\theta,\phi)$ ``measured'' over entire sphere

- accumulate strips over 27-day rotation
- hope that not much changes
- fill in poles (somehow)

$$\chi(r,\theta,\varphi) = \sum_{\ell,m} A_{\ell,m} \left[ \left(\frac{R_s}{r}\right)^{\ell+1} - \left(\frac{r}{R_s}\right)^{\ell} \right] Y_{\ell,m}(\theta,\varphi)$$

# PFSS model

(potential field source surface)



vol. I ch. 4

Solar wind flows from open field crossing $r=R_s$
… the `source' of the wind
➔ the `source surface'

$B_r(\theta,\phi)$ ``measured'' over entire sphere

- accumulate strips over 27-day rotation
- hope that not much changes
- fill in poles (somehow)
- decompose w/ spherical harmonics
- coeffs. ➔ $A_{l,m}$

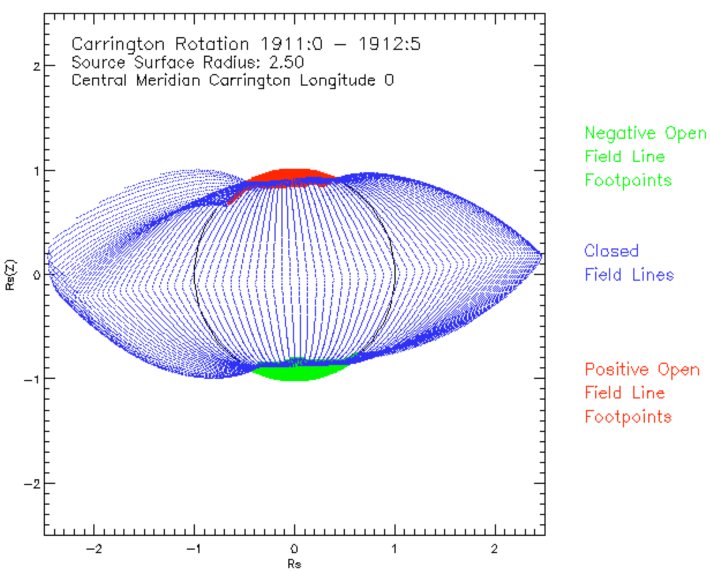
# Assumptions of the PFSS

- No currents in coronal field (simplest equilibrium)

$$\nabla \times \mathbf{B} = 0 \qquad R_o < r < R_s$$

- Field becomes open (radial) @ fixed radius $r{=}R_s$

- Not much change during 27-day accumulation



➔ **Model** distinguishing open/closed coronal field

➔ Field **actually** open will be source of solar wind, less dense & dark in EUX & SXR

# cosmic rays

- Originate far away in galaxy – in supernova remnant shocks
- Enter solar system isotropically
- No collisions with SW particles
- Deflected by SW **B**
  - Advected outward
  - Diffused by **B** fluctuations
  - Drift:

$$\mathbf{v}_d = \frac{pcw}{3q}\nabla\times\left(\frac{\mathbf{B}}{B^2}\right)$$

$$\approx \frac{2pcw}{3q}\frac{\mathbf{B}}{B^3}\times\nabla B$$

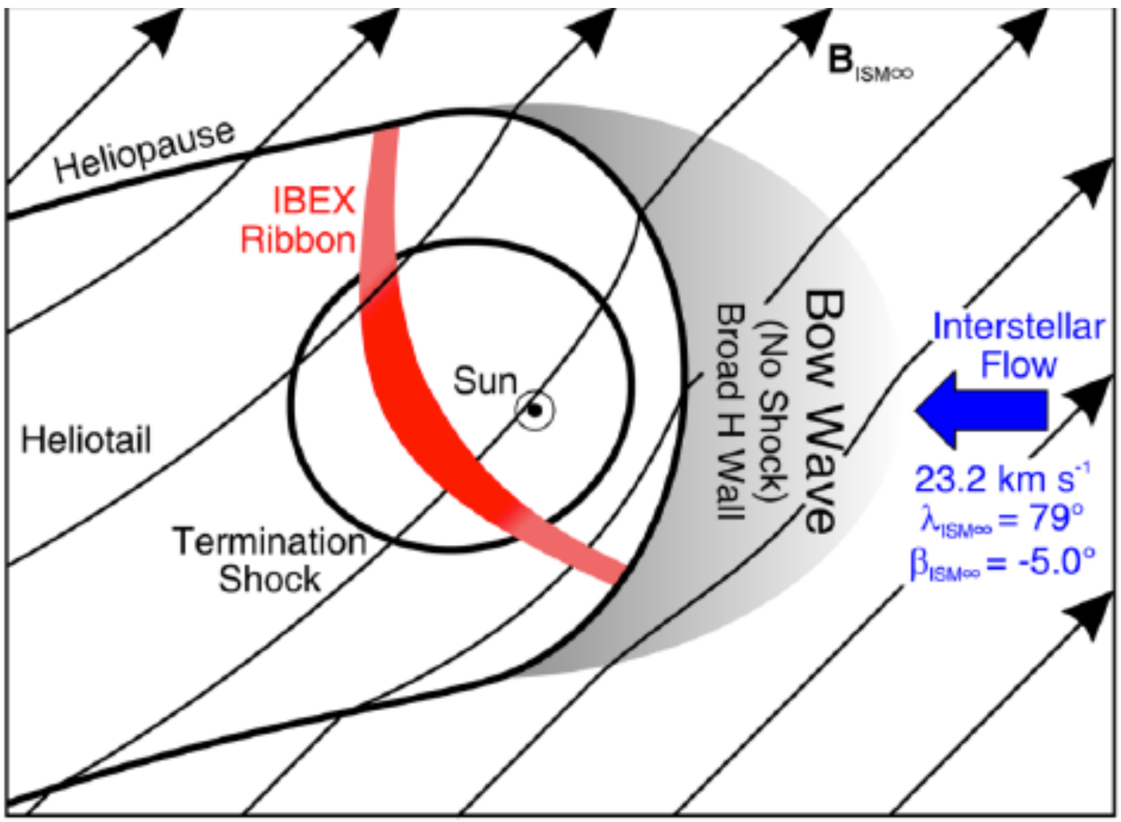
# The Heliosphere's Interstellar Interaction: No Bow Shock

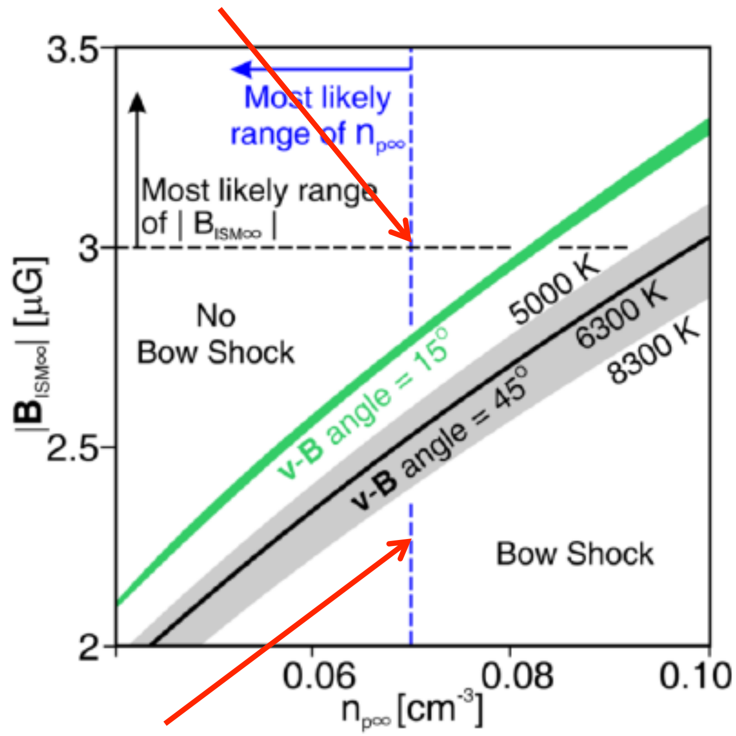
*Science* May 10, 2012

D. J. McComas,[1,2*] D. Alexashov,[3] M. Bzowski,[4] H. Fahr,[5] J. Heerikhuisen,[6] V. Izmodenov,[3] M. A. Lee,[7] E. Möbius,[7,8] N. Pogorelov,[6] N. A. Schwadron,[7] G. P. Zank[6]

**Result from IBEX**



$v_{fms}$ = 26.8 km/s



$v_{fms}$ = 21.4 km/s

# Summary

- Corona: because there is heating – reaches high T because radiation cannot balance heating so conduction is needed
- More heat ➔ higher density
- Wind: because there is heating – advective energy flux balances heating
- Creates heliosphere
